Abelian Varieties

These are notes for BUNTES Fall 2017, the topic is Abelian varieties, they were last updated September 10, 2019. We are using Milne’s abelian varieties notes primarily, for more details see the webpage. These notes are by Alex, feel free to email me at alex.j.best@gmail.com to report typos/suggest improvements, I’ll be forever grateful.

1.1 Introduction (Angus)

1.1.1 Definitions

Definition 1.1.1 Abelian varieties. An abelian variety is a complete connected algebraic group.

Definition 1.1.2 Algebraic groups. An algebraic group is an algebraic variety $G$ along with regular maps $m: G \times G \rightarrow G$, $e: * \rightarrow G$, $\text{inv}: G \rightarrow G$ such that the following diagrams commute.

Identity

![Identity Diagram]

Inverse

![Inverse Diagram]

Associativity

![Associativity Diagram]

Definition 1.1.3 Complete varieties. A variety $X$ is complete if every projec-
Example 1.1.4 Abelian varieties.

- Elliptic curves.
- Weil restriction $\text{Res}_{k/Q} E$ of an elliptic curve $E$.
- Jacobian varieties of curves.

Plan:

- Some motivation via elliptic curves.
- Gathering some material about “completeness”.
- Prove that abelian varieties are abelian.

1.1.2 Elliptic curves ($\text{char}(k) \neq 2, 3$)

Theorem 1.1.5 TFAE for a projective curve $E$ over $k$.

1. $E$ is given by $Y^2Z = X^3 + aXZ^2 + bZ^3$, $4a^3 + 27b^2 \neq 0$.
2. $E$ is nonsingular of genus 1 with a distinguished point $P_0$.
3. $E$ is nonsingular with an algebraic group structure.
4. (if $k \subseteq \mathbb{C}$) such that $E(\mathbb{C}) = \mathbb{C}/\Lambda$ for some lattice $\Lambda \subseteq \mathbb{C}$.

Proof. Strategy: Item 1 $\iff$ Item 2 $\iff$ Item 3 and Item 2 $\implies$ Item 4 $\implies$ Item 1.

Item 1 $\implies$ Item 2 is done.

Item 2 $\implies$ Item 1: Riemann-Roch states that $l(D) = l(K-D)+\deg(D)+1-g$ so here $l(D) = l(K-D) + \deg(D)$ further is $D > 0$ then $l(K-D) = 0$ in which case $l(D) = \deg(D)$. Consider $L(nP_0)$ for $n > 0$ Riemann-Roch implies that $l(nP_0) = n$ then it always contains the constants.

$L(P_0) = k$

$L(2P_0) = k \oplus kx$

$L(3P_0) = k \oplus kx \oplus ky$

$\vdots$

$L(6P_0) = k \oplus kx \oplus ky \oplus kx^2 \oplus ky^2 \oplus kxy \oplus kx^3 / \sim$

so we must have a relation which after manipulation is of the desired form. We get an embedding

$E \hookrightarrow \mathbb{P}^2$

$P \mapsto (x(P) : y(P) : 1) (P \neq P_0)$

$P_0 \mapsto (0 : 1 : 0)$

and thus $E$ is of the desired form. $\blacksquare$

Definition 1.1.6 Elliptic curves. An elliptic curve over $k$ is any/all of that 1.1.5.

Which of the above characterisations generalise to abelian varieties?
1. No, in general we don’t know that the equations look like.
2. One could possibly replace “genus” with a condition on the dimension of cohomology groups.
3. Yes, this is essentially the definition.
4. Yes, stay tuned!

### 1.1.3 Complete varieties

Idea: if $X \times Y$ had product topology (instead of its Zariski topology) then complete is equivalent to compact.

We’d like to gather a few results about complete varieties we can use to access properties of abelian varieties (like abelianness).

**Proposition 1.1.7** Let $V$ be a complete variety. Given any morphism $\phi: V \to W$, $\phi(V)$ is closed.

*Proof.* Let $\Gamma_\phi = \{(v, \phi(v))\} \subseteq V \times W$ be the graph of $\phi$. Its a closed subvariety of $V \times W$. Under the projection $V \times W \to W$, the image of $\Gamma_\phi$ is $\phi(V)$ and thus closed. ■

**Corollary 1.1.8** If $V$ is complete and connected, any regular function on $V$ is constant.

*Proof.* A regular function is a morphism $f: V \to A^1$. By the above $f(V) \subseteq A^1$ is closed, and this is a finite set of points. But connected implies we just have one point. ■

**Corollary 1.1.9** Let $V$ be a complete connected variety. Let $W$ be an affine variety. Given $\phi: V \to W$, then $\phi(V)$ is a point.

*Proof.* We have an embedding $W \hookrightarrow A^n$. On $A^n$ we have the coordinate functions $A^n \xrightarrow{\text{proj}} A^1$. The composition

$$V \xrightarrow{\phi} W \hookrightarrow A^n \xrightarrow{\text{proj}} A^1$$

be the above is constant. Thus the coordinates of $\phi(V)$ are constant, so $\phi(V) = \{\text{pt}\}$. ■

A final result of interest that I won’t prove today:

**Theorem 1.1.10** Projective varieties are complete.

The main goal of this section is to prove the following theorem:

**Theorem 1.1.11** Rigidity. Let $V, W$ be varieties such that $V$ is complete and $V \times W$ is geometrically irreducible. Let $\alpha: V \times W \to U$ be a morphism such that $\exists u_0 \in U(k), v_0 \in V(k), w_0 \in W(k)$ with $\alpha(V \times \{w_0\}) = \alpha(V \times \{v_0\}) = \{u_0\}$. Then $\alpha(V \times W) = \{u_0\}$.

*Proof.* Since $V \times W$ is geometrically irreducible, $V$ must be connected. Denote the projection $q: V \times W \to W$. Let $U_0 \ni u_0$ be an open neighborhood. We consider the set

$$Z = \{w \in W : \alpha((v, w)) \notin U_0 \text{ for some } v \in V\} = q(\alpha^{-1}(U \setminus U_0))$$

Since $q$ is closed, $Z \subseteq W$ is closed. Since $w_0 \in W \setminus Z$, $W \setminus Z$ is a nonempty open subset of $W$.

Consider $w \in W \setminus Z$. Since $V \times \{w\} \cong V$ it is complete and connected. Thus

$$\alpha(V \times \{w\}) = \{\text{pt}\} = \alpha((v_0, w)) = \{u_0\}$$

which implies that

$$\alpha(V \times (W \setminus Z)) = \{u_0\}$$
Since \( V \times (W \setminus Z) \subseteq V \times W \) is open and \( V \times W \) is irreducible, it is dense. So \( \alpha(V \times W) = \{ u_0 \} \).

**Proposition 1.1.12** Let \( A, B \) be abelian varieties. Every morphism \( \alpha : A \to B \) is the composition of a homomorphism and a translation.

**Proof.** First compose by a translation on \( B \) such that \( \alpha(0) = 0 \). Consider the map

\[
\phi : A \times A \to B \\
(a, a') \mapsto \alpha(a + a') - \alpha(a) - \alpha(a')
\]

Then

\[
\phi(A \times \{0\}) = \alpha(a + 0) - \alpha(a) - \alpha(0) = 0 \\
\phi(\{0\} \times A) = \alpha(0 + a) - \alpha(0) - \alpha(a) = 0.
\]

By the rigidity theorem 1.1.11 \( \phi(A \times A) = \{0\} \) hence \( \alpha(a + a') = \alpha(a) + \alpha(a') \).

**Corollary 1.1.13** Abelian varieties are abelian.

**Proof.** The inversion map \( a \mapsto -a \) sends \( 0 \) to \( 0 \), thus is a homomorphism. Therefore

\[
a + b - a - b = a + b - (a + b) = 0
\]

and so

\[
a + b = b + a.
\]

### 1.2 Abelian varieties over \( \mathbb{C} \) (Alex)

The goal of this talk is to understand what abelian varieties look like over \( \mathbb{C} \). The goal for me is to understand what a (principal) polarisation is and why it is important.

First immediate question: why study complex theory at all? The most classical field, algebraically closed, archimidean, characteristic 0.

Recall/rapidly learn the picture for elliptic curves, given \( E \) an elliptic curve we have for some \( \Lambda \) a rank 2 lattice in \( \mathbb{C} \)

\[
\mathbb{C}/\Lambda \to E(\mathbb{C}) \subseteq \mathbb{P}^2(\mathbb{C}) \\
z \mapsto (\varphi(z) : \varphi'(z) : 1) \\
0 \mapsto (0 : 1 : 0)
\]

where

\[
\varphi(z) = \frac{1}{z^2} + \sum_{\lambda \in \Lambda \setminus \{0\}} \frac{1}{(z - \lambda)^2} - \frac{1}{\lambda^2}.
\]

This is a meromorphic function whose image lands in

\[
y^2 = 4x^3 - g_2x - g_3.
\]

So the \( \mathbb{C} \) points of an elliptic curve are topologically a torus.

#### 1.2.1 Abelian varieties

Naturally one asks: does this generalise? Let \( A \) be an abelian variety over \( \mathbb{C} \), what does \( A(\mathbb{C}) \) look like? Another torus?
Proposition 1.2.1 \( A(\mathbb{C}) \) is a compact, connected, complex lie group.

Proposition 1.2.2 Let \( A \) be an abelian variety of dimension \( g \) over \( \mathbb{C} \). Then we have

\[ A(\mathbb{C}) \cong V/\Lambda \]

where \( V \) is a \( g \) dimensional complex vector space and \( \Lambda \) is a full rank lattice of \( V \) (i.e. \( \Lambda \) is a discrete subgroup of \( V \) s.t. \( \mathbb{R} \otimes \Lambda = V \)).

Proof. Differential geometry gives us a map of complex manifolds, the exponential map

\[ \exp : T_{gt}(0) A(\mathbb{C}) \to A(\mathbb{C}) \]

this is holomorphic. And since \( A(\mathbb{C}) \) is abelian, this is a homomorphism also. In general this is locally an isomorphism around 0.

Claim: \( \exp \) is injective. There exists a neighborhood \( U \supseteq 0 \) s.t. \( \exp(U) \neq U \). Consider the image \( \exp(T_{gt}(0) A(\mathbb{C})) \). For \( x \in \exp(T_{gt}(0) A(\mathbb{C})) \), \( \{U + x\} \) are all open and give a cover. Thus \( \exp(T_{gt}(0) A(\mathbb{C})) \) is open. Since \( A(\mathbb{C}) \) is connected we are thus reduced to showing \( \exp(T_{gt}(0) A(\mathbb{C})) \) is closed also. Since \( \exp \) is a homomorphism, the image is a subgroup. So its complement is the union of its non-trivial cosets, which is open. Thus \( \exp(T_{gt}(0) A(\mathbb{C})) \) is closed. Giving \( \exp(T_{gt}(0) A(\mathbb{C})) = A(\mathbb{C}) \), which proves the claim. \( \exp \) is a local isomorphism, which gives that \( \ker(\exp) \) is discrete, i.e. a lattice. We now have

\[ A(\mathbb{C}) \cong T_{gt}(0) A(\mathbb{C})/\ker(\exp) \]

so as \( A(\mathbb{C}) \) is compact we cannot have a kernel which is not full rank, as otherwise the quotient could not be compact. \( \blacksquare \)

Definition 1.2.3 We call any such \( V/\Lambda \) a complex torus. ♦

From the above isomorphism we can now read off properties of \( A(\mathbb{C}) \) as a group.

Proposition 1.2.4 \( A(\mathbb{C}) \) is divisible, and \( A(\mathbb{C})[n] \cong (\mathbb{Z}/n\mathbb{Z})^{2g} \).

Proof. \( A(\mathbb{C}) \cong V/\Lambda \cong (\mathbb{R}/\mathbb{Z})^{2g} \) isomorphisms as groups, thus \( A(\mathbb{C}) \) is divisible. Further, \( (\mathbb{R}/\mathbb{Z})[n] = (\mathbb{1}/n\mathbb{Z})/\mathbb{Z} \). \( \blacksquare \)

Question: Given a complex torus \( V/\Lambda \), does there exist an abelian variety \( A \) such that \( A(\mathbb{C}) \cong V/\Lambda \)?

Example 1.2.5

- \( \mathbb{C}/\Lambda \equiv E(\mathbb{C}) \) always in dim 1

- \( \mathbb{C}^2/\Lambda^2 \equiv (E \times E)(\mathbb{C}) \) sometimes yes in higher dimension

- \( \mathbb{C}^2/((i, 0), (i\sqrt{p}, i), (1, 0), (0, 1)) \mathbb{Z} \)

for \( p \) prime?? (I guess not, see Mumford)

Theorem 1.2.6 Chow. If \( X \) is an analytic submanifold of \( \mathbb{P}^n(\mathbb{C}) \) then \( X \) is an algebraic subvariety.
By this theorem it is enough to analytically imbed \( V/\Lambda \rightarrow \mathbb{P}^m \). We can try and do this by mimicing the elliptic curve strategy, find enough functions \( \theta: V/\Lambda \rightarrow \mathbb{C} \).

### 1.2.2 Cohomology

**Proposition 1.2.7** Let \( X = V/\Lambda \). Then

\[
H^r(X, \mathbb{Z}) \cong \{ \text{alternating } r\text{-forms } \Lambda \times \cdots \times \Lambda \rightarrow \mathbb{Z} \}.
\]

**Proof.** \( \pi: V \rightarrow V/\Lambda \) is a universal covering map, so

\[
\Lambda = \pi^{-1}(0) \cong \pi_1(X, 0).
\]

Because all these spaces are nice

\[
H^1(X, \mathbb{Z}) \cong \text{Hom}(\pi_1(X), \mathbb{Z}) \cong \text{Hom}(\Lambda, \mathbb{Z}).
\]

To extend to \( r \neq 1 \) use the Künneth formula:

\[
\bigoplus_{p+q=r}(\Lambda^p(H^1(X_1, \mathbb{Z})) \otimes \Lambda^q(H^1(X_2, \mathbb{Z}))) \cong H^r(X_1 \times X_2, \mathbb{Z}).
\]

Since we know the proposition for \( S^1 = \mathbb{R}/\mathbb{Z} \) by taking products and applying the above we get it for all complex tori \( V/\Lambda \).

**Proposition 1.2.8** There is a correspondence

\[
\{ \text{Hermitian forms } H \text{ on } V \} \leftrightarrow \{ \text{Alternating forms } E: V \times V \rightarrow \mathbb{R}, E(iu, iv) = E(u, v) \}
\]

\[
H \mapsto \text{im } H
\]

\[
E(iu, v) + iE(u, v) \leftrightarrow E.
\]

### 1.2.3 Line bundles

Now we will consider line bundles on \( X = V/\Lambda \), that is

\[
L \overset{\pi}{\rightarrow} X
\]

such that for any \( x \in X \) there exists \( U \ni x \) with \( \pi^{-1}(U) \cong \mathbb{C} \times U \). We can obtain these from hermitian forms and some auxiliary data as follows.

**Definition 1.2.9** If \( H \) is a hermitian form on \( V \) such that \( E(\Lambda \times \Lambda) \subseteq \mathbb{Z} \) there exists a map

\[
\alpha: \Lambda \rightarrow \mathbb{C}^* = \{ z \in \mathbb{C}^* : |z| = 1 \}
\]

such that

\[
\alpha(u + v) = e^{i\pi E(u, v)}\alpha(u)\alpha(v).
\]

Further, there is a line bundle \( L(H, \alpha) \) on \( X \) which is defined by quotienting \( \mathbb{C} \times V \) by \( \Lambda \) which acts via

\[
\phi_u(\lambda, v) = (\alpha(u)e^{\pi H(\lambda, u)}\alpha(u)^{-1}\pi H(\lambda, u)\lambda, v + u) \text{ for } u \in \Lambda,
\]
we’ll denote by $e_u$ the factor $\alpha(u) e^{\pi H(v, u) + \frac{1}{2} \pi H(u, u)}$ for brevity.

**Theorem 1.2.10 Appell-Humbert.** Any line bundle on $X$ is of the form $L(H, \alpha)$ for some $H, \alpha$ as above. Further

$$L(H_1, \alpha_1) \otimes L(H_2, \alpha_2) = L(H_1 + H_2, \alpha_1 \alpha_2).$$

In fact we have the following diagram

$$
\begin{array}{cccccc}
0 & \longrightarrow & \text{Hom}(\Lambda, \mathbb{C}) & \longrightarrow & \{\text{data } (H, \alpha)\} & \longrightarrow & \{\text{gp. of Herm. } H \text{ w/ } E(\Lambda \times \Lambda) \subseteq \mathbb{Z}\} & \longrightarrow & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow \\
0 & \longrightarrow & \text{Pic}^0(X) & \longrightarrow & \text{Pic}(X) & \longrightarrow & \ker(H^2(X, \mathbb{Z}) \rightarrow H^2(X, \mathcal{O}_X)) & \longrightarrow & 0 
\end{array}
$$

where Pic(X) is the group of all line bundles on $X$ and Pic$^0$ is the subgroup of those which are topologically trivial.

We wanted functions $X \rightarrow \mathbb{C}$. Now we can instead consider sections $s$ of $L(H, \alpha) \rightarrow X$ i.e. maps $s : X \rightarrow L(H, \alpha)$ with $\pi \circ s = \text{id}$. Denote the space of such sections $H^0(X, L(H, \alpha))$.

**Definition 1.2.11 Theta functions.** The sections of $L(H, \alpha)$ correspond to holomorphic functions

$$\theta : V \rightarrow \mathbb{C}$$

such that $\theta(z + u) = e_u \theta(z)$, we will call such a $\theta$ a **theta function** for $(H, \alpha)$. ♦

If $H$ is not positive definite the space of such functions is $0$!

**Proposition 1.2.12** If $H$ is positive definite, then the dimension of $H^0(X, L(H, \alpha))$ is $\sqrt{\det E}$ where we really mean the determinant of a matrix for $E$ with respect to an integral basis.

**Theorem 1.2.13 Lefschetz.** Given a positive definite $H$, there exists an imbedding $X \hookrightarrow \mathbb{P}^w$.

**Proof.** Sketch: Let $L = L(H, \alpha)$, consider $L(H, \alpha)^{\otimes 3} = L(3H, \alpha^3)$, take a basis of $\theta_0, \ldots, \theta_d$ of $H^0(X, L^{\otimes 3})$.

Claim: $\Theta : z \mapsto (\theta_0(z) : \cdots : \theta_d(z)) \subseteq \mathbb{P}^d$ is an embedding.

To see that this is well defined, we must give a section of $L^{\otimes 3}$ not vanishing at $z$ for all $z \in X$. Let $\theta \in H^0(X, L) \setminus \{0\}$. Then pick $a, b$ such that the section of $L^{\otimes 3}$ given by

$$\theta(z - a) \theta(z - b) \theta(z + a + b)$$

does not vanish. This is possible and thus we have a nonvanishing section of $L^{\otimes 3}$

For injectivity, show that if the above section has the same values on $z_1, z_2$ then it is a theta function for some sublattice. Almost all sections aren’t theta functions for a sublattice (this uses Proposition 1.2.12).

Something similar must be done for tangent vectors. ♦

**Definition 1.2.14 Riemann forms.** A Riemann form is $E : \Lambda \times \Lambda \rightarrow \mathbb{Z}$ alternating such that

$$E_R : V \times V \rightarrow \mathbb{R}$$

has the property that $E(iu, iv) = E(u, v)$ and the corresponding Hermitian form is positive definite. ♦
Definition 1.2.15 Polarizable tori. A complex torus $X = V/\Lambda$ is **polarizable** if there exists a Riemann form $E$ on $\Lambda$.

Example 1.2.16 Proposition. Every $\mathbb{C}/\Lambda$ where $\Lambda = \langle 1, \tau \rangle \mathbb{Z}$ is polarizable.
To see this take $E(u, v) = \frac{u \overline{v}}{\mathrm{im} \tau}$ as a Riemann form.

Putting everything together we have obtained an equivalence of categories

$\{\text{abelian varieties over } \mathbb{C}\} \leftrightarrow \{\text{polarizable complex tori}\}$.

1.2.4 Isogenies

Definition 1.2.17 Isogenies of complex tori. An **isogeny** of complex tori is a homomorphism $V/\Lambda \to V'/\Lambda'$ with finite kernel.

Definition 1.2.18 Dual vector spaces. Given $V$ a complex vector space, let

$V^* = \{ f : V \to \mathbb{C} : f(u + v) = f(u) + f(v), f(\alpha v) = \bar{\alpha} f(v) \}$

and given $\Lambda \subset V$ a lattice, let

$\Lambda^* = \{ f \in V^* : f(\lambda) \in \mathbb{Z} \forall \lambda \in \Lambda \}$.

Definition 1.2.19 Dual tori. If $X = V/\Lambda$, $X^\vee = V^*/\Lambda^*$ is the **dual torus**.

Proposition 1.2.20 Existence of Weil pairing.

$X \times X^\vee \to \mathbb{C}$

so

$X[n] \times X^\vee[n] \to \left( \frac{1}{n^2} \mathbb{Z}/\mathbb{Z} \right) \cong \mathbb{Z}/n\mathbb{Z}$

this is called the **Weil pairing**.

Can a complex torus be isogenous to its own dual? If $X$ is polarizable then

$X \to X^\vee$

$v \mapsto H(v, -)$

is an isogeny.

Definition 1.2.21 A **polarization** is an isogeny $X \to X^\vee$.

1.3 Rational Maps into Abelian Varieties (Maria)

Note all varieties are irreducible today.

1.3.1 Rational maps

$V, W$ varieties over $K$. Consider pairs $(U, \phi_U)$, where $\emptyset \neq U \subset V$ an open subset so $U$ is dense, and $\phi_U : U \to W$ is a regular map.
**Definition 1.3.1** **Rational maps.** \((U, \phi_U), (U', \phi_{U'})\) are equivalent if \(\phi_U\) and \(\phi_{U'}\) agree on \(U \cap U'\). An equivalence class \(\phi\) of \(\{(U, \phi_U)\}\) is a **rational map** \(\phi : V \to W\) if \(\phi : V \to W\) is defined at \(v \in V\) if \(v \in U\) for some \((U, \phi_U) \in \phi\). ♦

**Note 1.3.2** The set \(U_1 = \bigcup U\) where \(\phi\) is defined is open and \((U_1, \phi_1) \in \phi\) where \(\phi_1 : U_1 \to W\) restricts to \(\phi_U\) on \(U\).

**Example 1.3.3**

1. Let \(\emptyset \neq W \subseteq V\) be open. Then the rational map \(V \to W\) induced by \(id : W \to W\) will not extend to \(V\). To avoid this, assume \(W\) is complete (so \(W = V\)).

2. \(C : y^2 = x^3\), then \(\alpha : \mathbb{A}^1 \to C, a \mapsto (a^2, a^3)\) is a regular map, restricting to an isomorphism \(\mathbb{A}^1 \setminus \{0\} \to C \setminus \{0\}\). The inverse of \(\alpha|_{\mathbb{A}^1 \setminus \{0\}}\) represents \(\beta : C \to \mathbb{A}^1\) which does not extend to \(C\). This corresponds on function fields to \(K(t) \to K(x, y)\)

\(t \mapsto y/x\)

which does not send \(K[y][t]\) to \(K[x, y][x, y]\).

3. Given a nonsingular surface \(V, P \in V\) then \(\exists \alpha : W \to V\) regular that induces an isomorphism \(\alpha : W \setminus \alpha^{-1}(P) \to V \setminus P\), but \(\alpha^{-1}(P)\) is a projective line. The rational map represented by \(\alpha^{-1}\) is not regular on \(V\) (where to send \(P\)?).

\[\square\]

**Theorem 1.3.4** **Milne 3.1.** A rational map \(\phi : V \to W\) from a nonsingular variety \(V\) to a complete variety \(W\) is defined on an open subset \(U \subseteq V\) whose complement has codimension \(\geq 2\).

**Proof.** \((V\text{ a curve}) V\text{ nonsingular curve}, \emptyset \neq U \subseteq V\) open, \(\phi : U \to W\) a regular map.

\[
\begin{array}{ccc}
V & \to & W \\
p & & q \\
\downarrow & & \downarrow \\
U & \subset & Z \subseteq V \times W \\
p & & q \\
\downarrow & & \downarrow \\
U' \subseteq Z \subseteq V \times W & \ni (v, w) & W \ni w
\end{array}
\]

\(U'\) is the image of \(U, Z = \overline{U'}\). \(W\) is complete, \(Z\) closed implies \(p(Z) \subseteq V\) is closed. Also, \(U \subseteq p(Z) \implies p(Z) = V\).

\[
U \sim U' \to U
\]

so

\[
U' \sim U
\]

\[
Z \sim V
\]

this implies \(Z \sim V\). Then \(q|_Z : Z \to W\) is the extension of \(\phi\) to \(V\). ♦

**Theorem 1.3.5** **Milne 3.2.** A rational map \(\phi : V \to A\) from a nonsingular variety \(V\) to an abelian variety \(W\), extends to all of \(V\).

**Proof.** *Theorem 1.3.4* *Lemma 1.3.6*
**Lemma 1.3.6** Let \( \phi : V \rightarrow G \) be a map from a nonsingular variety to a group variety. Then either \( \phi \) is defined on all of \( V \) or the set where \( \phi \) is not defined is closed of pure codimension 1.

**Proof.** Fix \((U, \phi_U) \in \phi\) and consider

\[
\Phi : V \times V \rightarrow G
\]

represented by

\[
U \times U \xrightarrow{\phi_U \times \phi_U} G \times G \xrightarrow{\text{id} \times \text{inv}} G \times G \xrightarrow{m} G
\]

\[(x, y) \mapsto \phi_U(x)\phi_U(y)^{-1} \]

Check \( \phi \) is defined at \( x \) iff \( \Phi \) is defined at \((x, x)\) (and in this case \( \Phi(x, x) = e \)). This is equivalent to the map \( \Phi^* : O_{G,e} \rightarrow K(V \times V) \) induced by \( \Phi \) satisfying \( \text{im}(O_{G,e}) \subseteq O_{V \times V(x, x)} \) For a nonzero function \( f \) on \( V \times V \), write \( \text{div}(f) = \text{div}(f)_0 - \text{div}(f)_\infty \) which are effective divisors. Then

\[
O_{V \times V(x, x)} = \{0\} \cup \{f \in K(V \times V) : \text{div}(f)_\infty \text{ does not contain } (x, x)\}.
\]

Suppose \( \phi \) is not defined at \( x \), then there exists \( f \in \text{im}(O_{G,e}) \) s.t. \( (x, x) \in \text{div}(f)_\infty \). Then \( \Phi \) is not defined at any \( (y, y) \in \Delta \cap \text{div}(f)_\infty = \text{div}(f^{-1})_0 \), which is a pure codimension 1 subset of \( \Delta \) by Milne’s AG thm 9.2. The corresponding subset in \( V \) is of pure codimension 1, and \( \phi \) is not defined there.

**Theorem 1.3.7 Milne 3.4.** Let \( \alpha : V \times W \rightarrow A \) be a morphism from a product of nonsingular varieties into an abelian variety. If \( \alpha(V \times \{w_0\}) = \{a_0\} = \alpha(\{v_0\}) \times W \) for some \( a_0 \in A, v_0 \in V, w_0 \in W \), then \( \alpha(V \times W) = \{a_0\} \).

**Corollary 1.3.8 Milne 3.7.** Every rational map \( \alpha : G \rightarrow A \) from a group variety into an abelian variety is the composition of a homomorphism and a translation in \( A \).

**Proof.** Since group varieties are nonsingular, \( \alpha : G \rightarrow A \) is a regular map by **Theorem 1.3.5**. The rest is as proof of Corollary 1.2.

### 1.3.2 Dominating and birational maps

**Definition 1.3.9** Dominating maps. \( \phi : V \rightarrow W \) is dominating if \( \text{im}(\phi_U) \) is dense in \( W \) for a representative \((U, \phi_U) \in \phi\).

**Exercise:** A dominating \( \phi : V \rightarrow W \) defines a homomorphism \( K(W) \rightarrow K(V) \) and any such homomorphism arises from a unique dominating rational map.

**Definition 1.3.10** \( \phi : V \rightarrow W \) is birational if the corresponding \( K(W) \rightarrow K(V) \) is an isomorphism or, equivalently if there exists \( \psi : W \rightarrow V \) s.t. \( \phi \circ \psi \) and \( \psi \circ \phi \) are the identity wherever they are defined. In this case we say \( V \) and \( W \) are birationally equivalent.

**Note 1.3.11** In general birational equivalence does not imply isomorphic. E.g. \( V \) a variety \( \emptyset \neq W \subset V \) an open subset, or \( V = \mathbb{A}^1, W : y^2 = x^3 \).

**Theorem 1.3.12 Milne 3.8.** If two abelian varieties are birationally equivalent then they are isomorphic as abelian varieties.

**Proof.** \( A, B \) abelian varieties with \( \phi : A \rightarrow B \) a birational map with inverse \( \psi \). Then by **Theorem 1.3.5** \( \phi, \psi \) extend to regular maps \( \tilde{\phi} : A \rightarrow B, \tilde{\psi} : B \rightarrow A \) and \( \phi \circ \psi, \psi \circ \tilde{\phi} \) are the identity everywhere. This implies that \( \phi \) is an isomorphism of algebraic varieties and after composition with a translation, \( \phi \) is also a group isomorphism.
Proposition 1.3.13 Milne 3.9. Any rational map $A^1 \to A$ or $\mathbb{P}^1 \to A$, for $A$ an abelian variety is constant.

Proof. Theorem 1.3.5 implies $\alpha \colon A^1 \to A$ extends to $\alpha \colon A^1 \to A$ and we may assume $\alpha(0) = e$. ($A^1,+), \alpha(x+y) = \alpha(x) + \alpha(y)$ for all $x,y \in A^1(K) = K$. ($A^1 \setminus \{0\}, \cdot), \alpha(xy) = \alpha(x) + \alpha(y) + c$ for all $x,y \in K^x$. These can only hold at the same time if $\alpha$ is constant. $\mathbb{P}^1 \to A$ is constant, since its constant on affine patches.

Definition 1.3.14 $V/\overline{K}$ is unirational if there is a dominating map $A^n \to V$, where $n = \dim_{\overline{K}} V$. $V/K$ is unirational if $V/K$ is.

Proposition 1.3.15 Milne 3.10. Every rational map $V \to A$ from $V$ unirational to $A$ abelian is constant.

Proof. Wlog $K = \overline{K}$. Since $V$ is unirational we get $\beta \colon \mathbb{P}^1 \times \cdots \times \mathbb{P}^1 \to V \to A$, which extends to $\beta \colon \mathbb{P}^1 \times \cdots \times \mathbb{P}^1 \to A$. Then by Milne corollary 1.5, there exist regular maps $\beta_i \colon \mathbb{P}^1 \to A$ s.t. $\beta(x_1,\ldots,x_n) = \sum \beta_i(x_i)$ and by Proposition 1.3.13 each $\beta_i$ map is constant.

1.4 Theorem of the Cube (Ricky)

1.4.1 Crash Course in Line Bundles

Consider $\mathbb{R}^2, f : \mathbb{R} \to \mathbb{R}, f(x,y) = x^2 + y^2 - 1$, now $S = \{ f = 0 \} \subseteq \mathbb{R}^2$ is a closed submanifold (in fact a circle). Question: Do all closed submanifolds arise in this way? Let's switch to $\mathbb{C}$ better analogies with AG.

Example 1.4.1 Let $X \in \mathbb{P}^n(\mathbb{C})$, the answer here is no! (Because $f : X \to \mathbb{C}^1$ is constant!) Want to define functions locally that give us level sets, but gluing such will give us a global section. Instead glue in a different way (i.e. into different “copies” of $\mathbb{C}$) so that this doesn’t happen.

Example 1.4.2 $X \in P^1(\mathbb{C}), O_X$ the structure sheaf.

$$ X = U_0 \cup U_1 = (A^1,t) \cup (A^1,s) $$

on $U_0 \cap U_1$, $t = s^{-1}$. What is a global section of $O_X$, a section of $U_0$ and a section of $U_1$ that glue. $O_X(U_0) = k[t], O_X(U_1) = k[s]$ so given $f(t), g(s)$ these glue to a global section iff $f(t) = g(1/t)$ so $f,g$ must be constant.

Definition 1.4.3 Line bundles. A line bundle on $X$ is a locally free $O_X$-module of rank 1, i.e. $\exists \{ U_i \}$ open cover along with isomorphisms $\phi_i \colon \mathcal{L}|_{U_i} \to O_X|_{U_i}$.

Exercise 1.4.4 Alternative definition: A line bundle on $X$ is equivalent to the following data:

- An open cover of $X$.
- Transition maps $\tau_{ij} \in \text{GL}_1(O_X(U_i \cap U_j))$ satisfying $\tau_{ij} \tau_{jk} = \tau_{ik}$ and $\tau_{ii} = \text{id}$.

Example 1.4.5 On $X = \mathbb{P}^n_k$, we have line bundles $O(d)$ for all $d \in \mathbb{Z}$. Just have to give cover and transition functions, use usual open cover $\{U_i\}$ with $U_i \cong A^d$. Then $\tau_{ij}$ is given by multiplication by $(x_i/x_j)^d$.

Exercise 1.4.6

$$ H^0(X,O(d))(= \Gamma(X,O(d))) $$
Exercise 1.4.7 All line bundles on \( P^n \) are isomorphic to some \( O(d) \).

We say a line bundle \( L \) on \( X \) is trivial if \( L \cong O_X \). Given \( L_1 \) and \( L_2 \) on \( X \) (line bundles) we can create a new line bundle \( L = L_1 \otimes L_2 \). So isomorphism classes of line bundles on \( X \) with \( \otimes \) form a group, denoted \( \text{Pic}(X) \) with identity \( O_X \) and inverses \( L^{-1} = \text{Hom}(L, O_X) \).

Example 1.4.8 By previous exercise \( \text{Pic}(P^1_k) \cong Z \) since \( O_X(d_1) \otimes O_X(d_2) \cong O_X(d_1 + d_2) \).

Fact 1.4.9 If \( f : X \to Y \), then given \( L \) on \( Y \) we can pullback to a line bundle \( f^* L \) on \( X \), definition is complicated. We also know that \( f^* O_Y = O_X \) we get a homomorphism \( f^* : \text{Pic}(Y) \to \text{Pic}(X) \).

1.4.2 Relation to (Weil) divisors

Let \( X \) be a normal variety, call \( Z \subseteq X \), a closed subvariety of codimension 1, a prime divisor. Then a divisor on \( X \) is a formal sum

\[
D = \sum_{Z \subseteq X} n_Z \cdot Z
\]

of prime divisors.

Let \( K = K(X) \) be the function field of \( X \). Given \( f \in K^X \) we can define

\[
\text{div}(f) = \sum v_Z(f) \cdot Z.
\]

Given \( D \in \text{Div}(X) \), we can define a line bundle \( L(D) \) on \( X \) via

\[
L(D)(U) = \{ f \in K^X : (D + \text{div}(f))|_U \geq 0 \} \cup \{0\}
\]

where \( D|_U = \sum_{Z \cap U \neq \emptyset} n_Z \cdot (Z \cap U) \).

Proposition 1.4.10 The map

\[
\text{Cl}(X) = \text{Div}(X)/\text{Princ}(X) \xrightarrow{\mathcal{L}(\cdot)} \text{Pic}(X)
\]

is an isomorphism.

1.4.3 Onto cubes

Theorem 1.4.11 Theorem of the cube. Let \( U, V, W \) be complete varieties. If \( L \) is a line bundle on \( U \times V \times W \) s.t. \( L|_{U \times \{v\} \times W} \), \( L|_{U \times \{v_0\} \times W} \), \( L|_{U \times \{v\} \times \{w\}} \) are all trivial then \( L \) is trivial.

Corollary 1.4.12 Milne 5.2. Let \( A \) be an abelian variety. Let \( p_i : A \times A \times A \to A \) be the projection onto the \( i \)th coordinate. \( p_{ij} = p_i + p_j \), \( p_{123} = p_1 + p_2 + p_3 \). Then for any \( L \) on \( A \), the line bundle

\[
M = p_{123}^* L \otimes p_{12}^* L^{-1} \otimes p_{23}^* L^{-1} \otimes p_{13}^* L^{-1} \otimes p_1^* L \otimes p_2^* L \otimes p_3^* L
\]

is trivial.

Proof. Let \( m : A \times A \to A \) be multiplication (addition?) and \( p, q \) the projections \( A \times A \to A \). Then the composites of the maps \( \phi : A \times A \to A \times A \times A \), \( \phi(x, y) = (x, y, 0) \) with \( p_{123}, p_{12}, p_{23}, p_{13}, p_1, p_2, p_3 \) are respectively \( m, m, q, p, p, q, 0 \). Hence
the restriction of \( M \) to \( A \times A \times \{0\} \) is

\[
m' L \otimes m^* L^{-1} \otimes q^* L^{-1} \otimes p^* L^{-1} \otimes p^* L \otimes q L \otimes O_{A \times A} \]

this is trivial by tensor commuting with pullback. Similarly \( M \) restricts to a trivial bundle on \( A \times \{0\} \times A \) and \( \{0\} \times A \times A \). So by theorem of the cube 1.4.11 \( M \) is trivial.

**Corollary 1.4.13** Milne 5.3. Let \( f, g, h : V \to A \) (abelian). Then for any \( L \) on \( A \) the bundle

\[
M = (f + g + h)^* L \otimes (f + g)^* L^{-1} \otimes (f + h)^* L^{-1} \otimes (g + h)^* L^{-1} \otimes f^* L \otimes g^* L \otimes h^* L
\]

is trivial.

**Proof.** \( M \) is the pullback of the line bundle of Corollary 1.4.12 via the map \((f, g, h) : V \to A \times A \times A\). On \( A \) we have \( n_A : A \to A \) be \( n_A(a) = a + \cdots + a (n \text{ times}) \) for \( n \in \mathbb{Z} \).

**Corollary 1.4.14** Milne 5.4. For \( L \) on \( A \) we have

\[
n^*_A L \cong L^{(n^2 + n)/2} \otimes (-1)^* A L^{(n^2 - n)/2}
\]

In particular if \((-1)^* A L = L \) (symmetric) then \( n^*_A L = L^{n^2} \). And if \((-1)^* A L = L^{-1} \) (antisymmetric) then \( n^*_A L = L^n \).

**Proof.** Use Corollary 1.4.13 with \( f = n_A, g = 1_A, h = (-1)_A \). So the line bundle

\[
(n)^* L \otimes (n + 1)^* L^{-1} \otimes (n - 1)^* L^{-1} \otimes (1 - 1)^* L^{-1} \otimes n^* L \otimes 1^* L \otimes (-1)^* L
\]

is trivial i.e.

\[
(n + 1)^* L = (n - 1)^* L^{-1} \otimes n^* L^2 \otimes L \otimes (-1)^* L
\]

in statement \( n = 1 \) is clear, so use \( n = 1 \) in the above to get

\[
2^*_A L \cong L^2 \otimes L \otimes (-1)^* A L \cong L^3 \otimes (-1)^* A L.
\]

Then induct on \( n \) in above.

**Theorem 1.4.15** Theorem of the square (Milne 5.5). Let \( L \) be an invertible sheaf (line bundle) on \( A \). Let \( t_a : A \to A \) be translation by \( a \in A(k) \). Then

\[
t^*_a + b L \otimes L \cong t^*_a L \otimes t^*_b L.
\]

**Proof.** Use Corollary 1.4.13 with \( f = \text{id}, g(x) = a, h(x) = b \) to get

\[
t^*_a + b L \otimes t^*_a L^{-1} \otimes t^*_b L^{-1} \otimes L
\]

is trivial.

**Remark 1.4.16** Tensor by \( L^{-2} \) in the above equation to get

\[
t^*_a + b L \otimes L^{-1} \cong (t^*_a L \otimes L^{-1}) \otimes (t^*_b L \otimes L^{-1}).
\]

This gives a group homomorphism

\[
A(k) \to \text{Pic}(A)
\]

via

\[
a \mapsto t^*_a L \otimes L^{-1}
\]

for any \( L \in \text{Pic}(A) \).
1.5 The Adventures of BUNTES (Sachi)

1.5.1 In which we are introduced to an important homomorphism, review some concepts and our story begins

Abelian variety $X$, we know this is a complete group variety, our goal is to give an embedding $X \to \mathbb{P}^N$ for some $N$. This motivates the study of line bundles.

Last time Ricky proved theorem of cube 1.4.11 and square 1.4.15. For any line bundle $L$ on $X$, there is a group homomorphism $\Phi_L : X \to \text{Pic}(X)$ via $x \mapsto T^*_x L \otimes L^{-1}$. Be careful $T^*_x$ is $-x$, convention, who knows why.

Example 1.5.1 Let $X = E$ an elliptic curve, $L = L((0))$, $x \mapsto (x) - (0)$, in this case this is in $\text{Pic}^0(E) \cong E \cong \hat{E}$.

Proposition 1.5.2 This is translation invariant.

Proof. Translate by $q \in E$. $(x + q) - (q) \mapsto (x) - (0)$ or $(x) - (q)$.

What about the converse of this, what can we say about translation invariant line bundles

$K(L) = \{ x \in X : T^*_x L \equiv L \}$?

Proposition 1.5.3 $K(L)$ is Zariski closed in $X$.

Proof. Consider $m^*L \otimes p^*_x L^{-1}$ on $X \times X$, then

$\{ x : \text{this is trivial on } \{ x \} \times X \}$

is closed. See-saw 1.6.6 implies restriction is pullback

$T^*_x L \otimes L^{-1}$

so this is $K(L)$.

1.5.2 In which Pooh discovers our main theorem

Proposition 1.5.4 Let $X$ be an abelian variety and $L$ a line bundle, $L = L(D)$ then TFAE:

1. $H(D) = \{ x \in X : T^*_x D \equiv D \}$ is finite.
2. $K(L) = \{ x \in X : T^*_x L \equiv L \}$ is finite.
3. $|2D|$ is basepoint free and defines a finite morphism $X \to \mathbb{P}^N$.
4. $L$ is ample.

Proof.

3. to 4.. Is algebraic geometry.
2. to 1.. Follows as being equal is stronger than being linearly equivalent.
4. to 2.. Section 1.5.3
3. to 4.. Section 1.5.4
1.5.3 In which Owl proves the ampleness of \( L \) implies finiteness of \( K(L) \)

4. to 2. Assume \( L \) ample and \( K(L) \) is infinite. Let \( Y \) be the connected component at 0 of \( K(L) \), \( \dim Y > 0 \). Show trivial bundle is ample on \( Y \) implies \( Y \) is affine, but \( Y \) is closed and therefore complete so this is a contradiction. \( L|_Y \) ample \([-1]_Y \) is ample. \( L|_Y \otimes [-1]_Y \) is ample, consider

\[
d : Y \to Y \times Y \\
y \mapsto (y, -y)
\]

\( m \circ d = \text{constant}, d^* m^*(L) = O_Y \), LHS is \( L|_Y \otimes [-1]_Y \).

1.5.4 In which Rabbitt sets out on a long journey to prove finiteness of \( H(D) \) implies \( |2D| \) is basepoint free and gives a finite map \( X \to \mathbb{P}^N \)

Note 1.5.5 \(|2D| \) is always basepoint free.

Apply the theorem of the square 1.4.15: \( T_{x+y} D + D \equiv T_x D + T_y D \), let \( y = -x, 2D \equiv T_x D + T_y D \). \( (D \text{ effective}) \) For any \( y \in X \), choose some \( x \) s.t. RHS doesn’t contain \( y \). \( E = 2D \)

\[
\psi_E : X \to \mathbb{P}^N
\]

can we make this finite? If \( \psi_E \) is not finite then \( \psi(C) = \text{pt} \) for some irreducible curve \( C \) (Zariski’s main theorem). For each divisor in \(|E|\) either it contains \( C \) or fails to intersect \( C \) by changing \( E \) if necessary, assume \( E \cap C = \emptyset \).

Claim 1.5.6 \( T^*_x E \cap C = \emptyset \) or all of \( C \) for all \( x \in X \).

Proof. Intersection numbers are constant. ■

Proof. \( O(T^*_x E)|_C \), when \( x = 0 \) this is trivial so \( \deg = 0 \). So \( \deg = 0 \) for all line bundles. \( E \) effective implies \( C \cap T^*_x E = \emptyset \) for all \( x \) s.t. \( C \) is not in \( C \). ■

Claim 1.5.7 \( E \) is invariant by translation by \( x - y \) for \( x, y \in C \).

Proof. If \( e \in E, T_{x-e}(E) \cap C \neq \emptyset \). This is as \( x \) is in it, \( x - (x-e) = e \), because it is nonempty it’s all of \( C \). So \( y \) is in it. So \( y-(x-e) \in E \). This is also \( e-(x-y) \in E \), so \( E \) is invariant under \( T_{x-y} \) ■

Now assume \( H(E) = \{ x \in X : T^*_x E = E \} \) is finite. But if \( \psi_E(C) = \text{pt} \) then \( T^*_x E = E \) for all \( x, y \in C \). So \( H \) is not finite, a contradiction. So \( \psi_E \) can’t collapse a curve so \( \psi_E \) is finite.

1.5.5 In which Piglet discovers a corollary

Corollary 1.5.8 Abelian varieties are projective.

Proof. Let \( X \) be an abelian variety, \( U \subseteq X \) be an open affine set, \( 0 \in U \), \( X \setminus U = D_1 \cup \cdots \cup D_l \) irreducible divisors. Let \( D = \sum D_i \), then claim: \( H(D) = \{ x \in X : T^*_x D = D \} \) is finite. If \( H \subseteq U \), \( U \) affine, then \( H \) closed subvariety of an abelian variety, hence complete, so its finite. If \( x \in H \) then \( -x \in H \). Now claim that if \( x \in H \) then \( T^*_x \) preserves \( U \), if not let \( u \in U \). Suppose \( u - x = d \) for some \( d \in D \) then \( u = d + x \) which is \( d \) translated by \( -x \) so \( d + x \in D \) so \( u \in D \). But contradiction, oh no! So \( T^*_x \) preserves \( U \), for all \( x \in H \), as \( 0 \in U \), for all \( x \in H \) we have \( 0 - x \in U \) and \( 0 + x \in U \) so \( H \subseteq U \). ■

Corollary 1.5.9 Abelian varieties are divisible. \( X[n] \) is finite for \( n \geq 1 \).
Proof. \([n] : X \to X\) and \(X[n]\) is the kernel of this. Note that for \(x \in X[n]\)

\[[n] \circ T_x = [n]\]

\(y \in X\), then \(n(y - x) = ny - nx = ny\) so for all \(L \in \text{Pic} X\)

\(T_x^*([n]^*L) \cong ([n]^*L)\)

which implies

\(K([n]^*L) \supseteq X[n]\)

and we just need to find \(L\) s.t. this is finite. \(X\) projective implies there exists an ample \(L\). The theorem of the cube 1.4.11 implies

\([n]^*L \cong L^{\frac{n^2}{2}} \otimes L^{\frac{n^2}{2}}\)

where both terms on the right are ample, hence the left is also. \(\blacksquare\)

1.5.6 Epilogue: In which we might discuss isogenies

**Definition 1.5.10** \(f : X \to Y\) a morphism of varieties, get a field extension \(k(X)/f^*k(Y)\), if \(\dim X = \dim Y\) and \(f\) is surjective. Then this is a finite field extension and \(\deg f = d = |k(X) : f^*k(Y)|\) and \(d = #f^{-1}(y)\) for almost all \(y\). \(\diamondsuit\)

**Definition 1.5.11** A homomorphism of abelian varieties \(f : X \to Y\) is an isogeny if \(f\) is surjective with finite kernel. \(\diamondsuit\)

**Corollary 1.5.12** Degree of \([n]\) is \(n^{2g}\), if \(n\) is prime to the characteristic of \(k\), \(k = \overline{k}\), \(g = \dim X\).

*Proof.* Let \(D\) be an ample symmetric divisor, e.g.

\(D = D' + [-1]^*D'\)

know \([n]^*D \sim n^2D\)

\(\deg([n]^*(D \cdot \ldots \cdot D)) = ([n]^*D \cdot \ldots \cdot [n]^*D) = (n^2D \cdot \ldots \cdot n^2D) = n^{2g}(D \cdot \ldots \cdot D)\). \(\blacksquare\)

1.6 Line Bundles and the Dual Abelian Variety (An-gus)

1.6.1 Introduction

**Meta-goal.** Understand line bundles on abelian varieties.

**Setup.** \(A\) an abelian variety /\(k\).

**Last time.** For \(L\) a line bundle on \(A\) we get a map

\[\phi_L : A(K) \to \text{Pic}(A)\]

\[a \mapsto t_a^*L \otimes L^{-1}\]

where

\(\text{Pic}(A) = \{\text{line bundles on } A\}/\sim\).
This a is a group homomorphism (by the theorem of the square 1.4.15). We define
\[ K(L)(k) = \ker(\phi_L) = \{a \in A(k) : t^*_a L \approx L \}. \]

**Today.** We are going to package these into a big map
\[ \phi : \text{Pic}(A) \to \text{Hom}(A(k), \text{Pic}(A)) \]
\[ L \mapsto \phi_L. \]

**Proposition 1.6.1**
1. \( \phi \) is a group homomorphism
2. \( \phi_{L \otimes M} = \phi_L \phi_M \)

**Proof.**
1. 
\[
\phi_{L \otimes M}(a) = t^*_a (L \otimes M) \otimes (L \otimes M)^{-1} \\
= t^*_a L \otimes L^{-1} t^*_a M \otimes M^{-1} \\
= \phi_L \otimes \phi_M 
\]
2. 
\[
\phi_{t^*_a L}(a) = t^*_a (t^*_a L) \otimes (t^*_a L)^{-1} \\
= t^*_a t^*_a L \otimes (t^*_a L)^{-1} \\
= t^*_a L \otimes t^*_a L \otimes L^{-1} \otimes (t^*_a L)^{-1} \\
= \phi_L(a) 
\]
by the theorem of the square 1.4.15

**Definition 1.6.2**
\[ \text{Pic}^0(A) = \ker(\phi) \]
\[ = \{L \in \text{Pic}(A) : \phi_L = 0\} \]
\[ = \{L \in \text{Pic}(A) : t^*_a L \approx L \ \forall a \in A(k)\} \]
\[ = \{\text{translation invariant line bundles}\}/\sim \]

**Goals.** Study \( \text{Pic}^0(A) \), give it an abelian variety structure, solve a moduli problem, demonstrate some duality.

**1.6.2 Aside: alternate description of \( \text{Pic}^0(A) \)**

**Definition 1.6.3** Algebraic Equivalence. Two line bundles \( L_1, L_2 \) on an abelian variety are algebraically equivalent if there exists a variety \( Y \) with line bundle \( L \) on \( A \times Y \) and points \( y_1, y_2 \in Y \) s.t. \( L|_{A \times \{y_1\}} \approx L_1, L|_{A \times \{y_2\}} \approx L_2. \)

**Remark 1.6.4** This looks like homotopy.
Proposition 1.6.5

\[ \text{Pic}^0(A) = \{ \text{line bundles which are alg. equiv to } O_A \} \]

Proof. [70].

1.6.3 See-Saws

Theorem 1.6.6 See-saw theorem. Let \( X, T \) be varieties \( X \) complete, let \( L \) be a line bundle on \( X \times T \), let \( T_1 = \{ t \in T : L|_{X \times \{t\}} \text{ is trivial} \} \) then \( T_1 \) is closed in \( T \). Further let \( p_2: X \times T_1 \to T_1 \), then \( L|_{X \times T_1} \cong p_2^* M \) for some line bundle \( M \) on \( T_1 \).

Remark 1.6.7 In fact \( M \cong p_2^* L \).

Corollary 1.6.8 that no one states/only Milne. Let \( X, T \) be as above and let \( L, M \) be line bundles on \( X \times T \) s.t.

\[ L|_{X \times \{t\}} \cong M|_{X \times \{t\}} \forall t \in T \]

\[ L|_{\{t\} \times X} \cong M|_{\{t\} \times X} \text{ for some } x \in X \]

then \( L \cong M \).

1.6.4 Properties of \( \text{Pic}^0 A \)

Lemma 1.6.9 \( L \in \text{Pic}^0(A) \) and \( m, p_1, p_2: A \times A \to A \)

1. \( m^* L \cong p_1^* L \otimes p_2^* L \)

2. Given \( f, g: X \to A \)

\( (f + g)^* L \cong f^* L \otimes g^* L \)

3. \( [n]^* L \cong L^\otimes n \)

4. \( \phi_L(A(k)) \subseteq \text{Pic}^0(A) \)

for \( L \in \text{Pic}(A) \).

Proof.

1. \( (m^* L \otimes (p_1^* L)^{-1} \otimes (p_2^* L)^{-1})|_{A \times \{a\}} = t_a^* L \otimes L^{-1} = O_A \)

\( (m^* L \otimes (p_1^* L)^{-1} \otimes (p_2^* L)^{-1})|_{\{a\} \times A} = t_a^* L \otimes L^{-1} = O_A \)

by see-saw 1.6.6 whole thing is trivial on \( A \times A \).

2. \( (f + g)^* L \cong (f \times g)^* m^* L \cong (f \times g)^* (p_1^* L \otimes p_2^* L) \cong f^* L \otimes g^* L \)

3. Induction of 3.

4. \( \phi_{\phi_L(a)} = \phi_{t_a^* L} \otimes L^{-1} = \phi_{t_a^* L} \otimes L^{-1} = \phi_L \otimes \phi_{L^{-1}} = 0 \)

Proposition 1.6.10 If \( L \) is nontrivial in \( \text{Pic}^0(A) \) then \( H^i(A, L) = 0 \) \( \forall i. \)
Proof. If $H^0(A, L) \neq 0$, we would have a nontrivial section $s$ of $L$ then $[-1]^*s$ is a nontrivial section of $[-1]^*L = L^{-1}$. But if both $L$ and $L^{-1}$ have a nontrivial section then $L \cong O_A$. So since $L$ is nontrivial $H^0(A, L) = 0$. Now assume $H^i(A, L) = 0$ for all $i < j$. Consider

$$A \overset{id \times 0}{\longrightarrow} A \times A \overset{m}{\longrightarrow} A$$

$a \mapsto (a, 0) \mapsto a$

this gives

$$H^j(A, L) \to H^j(A \times A, m^* L) \to H^j(A, L)$$

which composes to the identity.

$$H^j(A \times A, m^* L) = H^j(A \times A, p_1^* L \otimes p_2^* L) = \bigoplus_{i=0}^j H^i(A, L) \otimes H^{j-i}(A, L)$$

by Künneth. The RHS is 0 by the inductive hypothesis. So the identity on $H^j(A, L)$ factors through 0, hence the group is 0.

We now think of $\phi_L$ as a map $\phi_L : A(k) \to \text{Pic}^0(A)$ with kernel $K(L)(k)$.

**Theorem 1.6.11** If $K(L)(k)$ is finite then $\phi_L$ is surjective.

**Proof.** Idea is to study

$$\Lambda(L) = m^* L \otimes (p_1^* L)^{-1} \otimes (p_2^* L)^{-1}.$$

Given an ample line bundle $L$ on $A$ we now have an isomorphism of groups

$$A(k)/K(L)(k) \cong \text{Pic}^0(A)$$

the LHS allows us to put an abelian variety structure on $\text{Pic}^0(A)$.

### 1.6.5 The Dual Abelian Variety

**Theorem 1.6.12** Let $A$ be an abelian variety and $L$ an ample line bundle on $A$, then the quotient scheme $A/K(L)$ exists and is an abelian variety of the same dimension as $A$.

**Proof.** (Sketch) (characteristic 0) Cover $A$ by affine opens $U_i = \text{Spec} R_i$ such that for all $a \in A$ the orbit $K(L)a \subseteq U_i$ for some $i$. We can do this because abelian varieties are projective. Then we say $U_i/K(L) = \text{Spec} (R_i^{K(L)})$ then glue. (details in Mumford, II sec, 6 appendix). Since we are in characteristic 0, the quotient scheme is in fact a variety.

**Definition 1.6.13** Dual abelian varieties. The dual abelian variety is

$$\hat{A} = A/K(L).$$

**Remark 1.6.14**

- $\hat{A}(K) = \text{Pic}^0(A)$
- We have an isogeny $\phi_L: A \to \hat{A}$.  

Theorem 1.6.15 There is a unique line bundle $\mathcal{P}$ on $A \times \hat{A}$ called the Poincaré bundle such that

1. $\mathcal{P}|_{A \times \{x\}} \in \text{Pic}^0(A)$ for all $x \in \hat{A}$
2. $\mathcal{P}|_{0 \times \hat{A}} = 0$
3. If $Z$ is a scheme with a line bundle $R$ on $A \times Z$ satisfying 1., 2., there exists a unique $f: Z \to \hat{A}$ s.t. $(\text{id} \times f)^* \mathcal{P} = R$.

That is $(\hat{A}, \mathcal{P})$ represents the functor

$$Z \mapsto \left\{ L \in \text{Pic}(A \times Z) : \left[ L|_{A \times \{x\}} \in \text{Pic}^0(A) \forall \{x\} \in Z \right] L|_{0 \times \{x\}} = 0 \right\} / \sim .$$

1.6.6 Dual morphisms

Let $f: A \to B$ be a homomorphism of abelian varieties. Let $\mathcal{P}_A, \mathcal{P}_B$ be the Poincaré bundles on $A$ and $B$. Consider $M = (F \times \text{id}_\hat{B})^* \mathcal{P}_B$ on $A \times \hat{B}$, then

1. $M|_{A \times \{x\}} \in \text{Pic}^0(A)$
2. $M|_{\{0\} \times \hat{B}} = 0$

thus by the universal property we get a unique morphism $\hat{f}: \hat{B} \to \hat{A}$ satisfying

$$(\text{id}_A \times \hat{f})^* \mathcal{P}_A = (f \times \text{id}_\hat{B})^* \mathcal{P}_B .$$

Definition 1.6.16 Dual morphisms. $\hat{f}$ as above is called the dual morphism.

Remark 1.6.17

- $\hat{f}: \hat{B} = \text{Pic}^0(B) \to \hat{A}(k) = \text{Pic}^0(A)$
  $$L \mapsto f^*L$$

- $[\hat{n}_A] = [n_A]$
  Consider the Poincaré bundle $\mathcal{P}_A$ on $\hat{A} \times \hat{A}$, now think of $\mathcal{P}_A$ as living on $\hat{A} \times A$. By the universal property of $\mathcal{P}_A$ get a unique morphism $\text{can}_A: A \to \hat{A}$.

Theorem 1.6.18 $\text{can}_A$ is an isomorphism.

Lemma 1.6.19

$$\phi_{f^*L} = \hat{f} \circ \phi_L \circ f .$$
Proposition 1.6.20 If \( f: A \to B \) is an isogeny, then \( \hat{f}: \hat{B} \to \hat{A} \) is an isogeny. Further if \( N = \ker f \), then \( \hat{N} = \ker \hat{f} \) is the Cartier dual of \( N \).

Definition 1.6.21 Symmetric morphisms, (principal) polarizations. A morphism \( f: A \to \hat{A} \) is symmetric if \( f = \hat{f} \circ \text{can}_A \). A polarization is a symmetric isogeny \( f: A \to \hat{A} \) s.t. \( f = \phi_L \) for some ample line bundle \( L \) on \( A \). A principal polarization is a polarization of degree 1, i.e. an isomorphism.

Remark 1.6.22 Elliptic curves always admit principal polarization. If one wishes to mimic the theory of elliptic curves, one should study principally polarized abelian varieties.

1.7 Endomorphisms and the Tate module (Berke)

Motivation.

\[
f: \mathbb{P}^n \subseteq V_1 \to V_2 \subseteq \mathbb{P}^m, \quad V_i = V(I_i) \quad P \mapsto \cdots
\]

\[
f = [f_1: \cdots: f_m], \quad f_i \in \overline{K}(V_1)
\]

this feels quite restrictive, an isogeny is even more so, rational, regular, homomorphism, surjective, finite kernel. It feels like there won’t be too many but we have multiplication by \( n \) etc. so we should ask how many are there that will surprise us? I.e. what is

\[
\text{rank}_\mathbb{Z} \text{Hom}(A, B) = ?
\]

Notation: \( A, B, C, A_i, B_i \) are all abelian varieties. \( l \neq \text{char} \, k, \sim \) is isogeny.

1.7.1 Poincaré’s complete reducibility theorem

Theorem 1.7.1 Poincaré’s complete reducibility theorem. Let \( B \subseteq A \) then there is \( C \subseteq A \) s.t. \( B \cap C \) is finite and \( B + C = A \). I.e. \( B \times C \to A, (b, c) \mapsto b + c \) is an isogeny.

Proof. Choose \( \mathcal{L} \) ample on \( A \)

\[
\begin{array}{ccc}
B & \xrightarrow{i} & A \\
\downarrow \phi_{\mathcal{L}} & & \downarrow \phi_{\mathcal{L}} \\
\hat{B} & \xleftarrow{i} & \hat{A}
\end{array}
\]

\( C \) is defined to be the connected component of \( \phi_{\mathcal{L}}^{-1}(\ker \hat{i}) \) in \( A \)

\[
\dim C = \dim \ker \hat{i} \geq \dim \hat{A} - \dim \hat{B} = \dim A - \dim B.
\]

\( B \cap C \) finite, \( z \in B, z \in B \cap \phi_{\mathcal{L}}^{-1}(\ker \hat{i}) = T^*_z \mathcal{L} \otimes \mathcal{L}^{-1} |_B \) is trivial if and only if \( z \in K(\mathcal{L} |_B) \). So \( \mathcal{L} |_B \) ample implies \( K(\mathcal{L} |_B) \) finite and so \( B \cap C \) is finite. So \( B \times C \to A \) has finite kernel and

\[
\dim(B \times C) = \dim B + \dim C \geq \dim A
\]

and surjective implies its an isogeny. 

\[\blacksquare\]
Definition 1.7.2 Simple abelian varieties. $A$ is called simple if there does not exist $B \subseteq A$ other than $B = 0, A$.

Corollary 1.7.3

$$A \sim A_1^{n_1} \times \cdots \times A_k^{n_k}$$

$A_i \sim A_j$ for $i \neq j$ and $A_i$ simple.

Corollary 1.7.4 $\alpha \in \text{Hom}(A, B)$ for $A, B$ simple then $\alpha$ is an isogeny or $0$.

Proof. $\alpha(A) \subseteq B$ which implies $\alpha(A) = B$ or $0$. The connected component of $0$ of $\ker \alpha$ will be an abelian subvariety of $A$, denote it $C$. If $C = A$ then $\alpha = 0$. So $\alpha$ is an isogeny or $0$. ■

Corollary 1.7.5 If $A, B$ are simple and $A \sim B$ then $\text{Hom}(A, B) = 0$.

Definition 1.7.6

$$\text{End}^0(A) = \text{End}(A) \otimes \mathbb{Q}.$$ 

Lemma 1.7.7 If $\alpha: A \rightarrow B$ is an isogeny, then there exists $\beta: B \rightarrow A$ s.t. $\beta \circ \alpha = n_A$ for some $n \geq 1$.

Proof. $\alpha$ an isogeny implies $\ker \alpha$ is finite. So there exists $n$ with $n \ker \alpha = 0$. $\ker \alpha \subseteq \ker n_A$.

$$\begin{array}{c}
A \xrightarrow{\alpha} A \\
\downarrow \quad \quad \quad \downarrow \circ \\
B \rightarrow A/\ker \alpha \\
\downarrow \beta \\
A/n_A
\end{array}$$

so $\beta \circ \alpha = n_A$, also $\alpha \circ \beta = n_B$. ■

Corollary 1.7.8 $A$ is simple then $\text{End}^0(A)$ is a division ring, $\alpha^{-1} = \beta \otimes \frac{1}{n}$.

Corollary 1.7.9 to Poincaré reducibility theorem. If

$$A \sim A_1^{n_1} \times \cdots \times A_k^{n_k}$$

then

$$\text{End}^0(A) \simeq \prod \text{End}^0(A_i)^{n_i^2}.$$ 

Proof.

$$\text{End}(A) \otimes \mathbb{Q} \simeq \prod \text{Hom}(A_i^{n_i}, A_j^{n_j}) \otimes \mathbb{Q}$$

$$\simeq \prod \text{End}(A_i)^{n_i^2} \otimes \mathbb{Q}$$

$$\simeq \prod \text{End}^0(A_i)^{n_i^2}$$

Theorem 1.7.10 7.2. If $\dim A = g$ then $\deg n_A = n^{2g}$.

Corollary 1.7.11 $\text{char } k \nmid n$ implies $\ker(n_A) \simeq (\mathbb{Z}/n\mathbb{Z})^{2g}$.

Proof. If $m|n$ then $|\ker(m_A)| = m^{2g}$, then use structure theorem. ■
In particular if we let $A[l^n] = A(k^{sep})[l^n]$, then $A[l^n] \cong (\mathbb{Z}/l^n)^{\mathfrak{g}}$ Define

$$T_i(A) = \lim_{\longrightarrow} A[l^n], A[l^{n+1}] \rightarrow A[l]$$

**Proposition 1.7.12**

$T_i \cong (\mathbb{Z}_l)^{\mathfrak{g}}$

$a : A \rightarrow B$ induces

$$T_i\alpha : T_i(A) \rightarrow T_i(B)$$

$$(a_1, a_2, \ldots) \mapsto (\alpha(a_1), \alpha(a_2), \ldots)$$

**Lemma 1.7.13**

$\text{Hom}(A, B) \hookrightarrow \text{Hom}(T_i(A), T_i(B))$

**Proof.** Let $\alpha \in \text{Hom}(A, B)$ and assume $T_i\alpha = 0$ then

$$\ker(\alpha|_{A_i}) \supseteq A_i[l^n]\forall n$$

for any simple component $A_i$ of $A$ so $\alpha = 0$ on each $A_i$ and hence $\alpha = 0$ on $A$. ■

**Corollary 1.7.14** $\text{Hom}(A, B)$ is torsion free.

Recall we are interested in knowing about $\text{rank}_{\mathbb{Z}} \text{Hom}(A, B) = ?$, can we bound this? If we could show that

$$\text{Hom}(A, B) \otimes \mathbb{Z}_l \hookrightarrow \text{Hom}(T_i(A), T_i(B))$$

we could conclude, so:

$$\xymatrix{ \text{Hom}(A, B) \otimes \mathbb{Z}_l \ar[r] \ar[d] & \text{Hom}(T_i A, T_i B) \ar[d] \\
\prod_{i,j} (\text{Hom}(A_i, B_j) \otimes \mathbb{Z}_l) \ar[r] & \prod_{i,j} \text{Hom}(T_i A_i, T_i B_j)}$$

$A_i + B_j = 0, A_i \sim B_j \text{ Hom}(A_i, B_j) \hookrightarrow \text{End}(A_i)$. Assume $A = B$ and $A$ simple, then $\text{End}(A) \otimes \mathbb{Z}_l \hookrightarrow \text{End}(T_i(A))$.

**Definition 1.7.15** $V/k$ then $f : V \rightarrow k$ is called a (homogenous) polynomial function of degree $d$ if $\forall \{v_1, \cdots, v_m\} \subseteq V$ linearly independent.

$$f(\lambda_1 v_1 + \lambda_2 v_2 + \cdots + \lambda_m v_m)$$

is given by a homogenous polynomial of degree $d$ in $\lambda_i$ i.e.

$$f(\lambda_1 v_1 + \lambda_2 v_2 + \cdots + \lambda_m v_m) = P(\lambda_1, \ldots, \lambda_m)$$

for some $P \in k[X_m]$ homogenous of degree $d$. ♦

$$\deg : \text{End}(A) \rightarrow \mathbb{Z}$$

$a$ an isogeny iff $\deg a = \alpha$ not an isogeny iff $0$.

**Theorem 1.7.16** $\deg$ uniquely extends to a polynomial function of degree $2g$ on $\text{End}^0(A) \rightarrow \mathbb{Q}$.

**Proof.** (of above continued)

$$\text{End}(A) \otimes \mathbb{Z}_l \hookrightarrow \text{End}(T_i(A))$$
for $A$ simple iff for any finitely generated $M \subseteq \text{End}(A)$

$$M \otimes \mathbb{Z}_l \hookrightarrow \text{End}(T_l(A))$$

Claim:

$$M^{\text{div}} = \{ f \in \text{End}(A) : nf \in M \text{ for some } n \geq 1 \}$$

is finitely generated.

Proof: $M^{\text{div}} = (M \otimes \mathbb{Q}) \cap \text{End}(A)$ deg: $M \otimes \mathbb{Q} \rightarrow \mathbb{Q}$ is a polynomial so it is continuous.

$$U = \{ \phi \in M \otimes \mathbb{Q} : \deg \phi < 1 \}$$

is open in $M \otimes \mathbb{Q}$ but $U \cap M^{\text{div}} = 0$ so $M^{\text{div}}$ is a discrete subgroup of the finite dimensional $\mathbb{Q}$-vector space $M \otimes \mathbb{Q}$ so $M^{\text{div}}$ is finitely generated. $M \hookrightarrow M^{\text{div}}$ so $M \otimes \mathbb{Z}_l \hookrightarrow M^{\text{div}} \otimes \mathbb{Z}_l$ so we may assume $M = M^{\text{div}}$.

Let $f_1, \ldots, f_r$ be a $\mathbb{Z}$-basis for $M$ and suppose that $\sum a_i T_l(f_i) = 0$ for some $a_i \in \mathbb{Z}_l$ not all 0. We can assume not all $a_i$ are divisible by $l$. Choose $a'_i \in \mathbb{Z}$ s.t. $a'_i \equiv a_i \pmod{l}$

$$f = \sum a'_i f_i \in \text{End}(A)$$

we then have

$$f = \sum a'_i T_l f_i$$

is 0 on the first coordinate of $T_l$. So $A[f] \subseteq \ker f$ so there exists $g$ with $f = lg$ $f \in M$ implies $g \in M^{\text{div}} = M$ so $g = \sum b_i f_i$ and $f = \sum lb_i f = \sum a_i f_i$ hence $l \mid a_i$ for all $i$ a contradiction. So $\text{End}(A) \otimes \mathbb{Z}_l \hookrightarrow \text{End}(T_l(A))$.

Therefore

$$\text{Hom}(A, B) \otimes \mathbb{Z}_l \hookrightarrow \text{Hom}(T_l(A), T_l(B))$$

$$\text{rank}_\mathbb{Z} \text{Hom}(A, B) \leq 4 \dim A \dim B.$$

\[\boxed{\text{1.8 Polarizations and \textit{Étale} cohomology (Alex)}}\]

Plan: polarizations, a little cohomological warmup and a cool finiteness result. \textit{Étale} cohomology.

1.8.1 Polarizations

Definition 1.8.1 Polarizations. A polarization of an abelian variety $A/k$ is an isogeny

$$\lambda : A \rightarrow \hat{A}$$

such that

$$\lambda \equiv \lambda _L : a \mapsto t^*_a \mathcal{L} \otimes \mathcal{L}^{-1}$$

for an ample invertible sheaf $\mathcal{L}$ on $A^\vee$.

We then have a notion of degree, polarizations of degree 1 (i.e. isomorphisms $A \rightarrow \hat{A}$) are called principal polarizations. \[\diamond\]

Remark 1.8.2 This is in fact equivalent to the previous definition 1.6.21, see [87, cor. 11.5].

Natural questions: what does the line bundle $\mathcal{L}$ tell us about the polarization? Can we tell principality?

To answer this we must (rapidly) recall (Zariski) sheaf cohomology. But this will help us in the next section too.
A line bundle (or indeed any sheaf) defines for us for any open subset $U \hookrightarrow X$ an abelian group of sections $\mathcal{L}(U)$.

However taking (global) sections doesn’t play well with exact sequences!

**Example 1.8.3 Classic example.** Let $X = \mathbb{C}^*$ and consider

$$0 \to \mathbb{Z} \hookrightarrow \mathcal{O}_X \xrightarrow{2\pi i -} \mathcal{O}'_X \to 0$$

but

$$0 \to \mathbb{Z} \to \mathcal{O}_X(X) \to \mathcal{O}'_X(X)$$

is not surjective on the right, for example $f(z) = z$ is a nowhere vanishing meromorphic function on $X$ but its not exp of anything. Upshot: maps of sheaves can be surjective (by being so locally) but not globally. □

To understand/control this phenomenon we introduce $H^1(X, \mathcal{F})$ fitting into the above and so on.

Explicitly: for a sheaf $\mathcal{F}$ we fix an injective resolution $0 \to \mathcal{F} \to I_0 \to I_1 \to \cdots$ which we then take global sections of to get a chain complex

$$0 \to \Gamma(X, \mathcal{F}) \to \Gamma(X, I_0) \to \Gamma(X, I_1) \to \cdots$$

and we truncate and take cohomology of this to measure “failure of exactness”

$$H^0(X, \mathcal{F}), H^1(X, \mathcal{F}), H^2(X, \mathcal{F}), \ldots.$$  

**Definition 1.8.4 Euler-Poincaré characteristic.** Define the Euler-Poincaré characteristic of a line bundle $L$ to be

$$\chi(L) = \sum (-1)^i \dim_k H^i(A, L).$$

**Theorem 1.8.5 Riemann-Roch.** Let $A$ be an abelian variety of dimension $g$ then

1. The degree of $\lambda_L$ is $\chi(L)^2$.
2. If $L = L(D)$ then $\chi(L) = (D^g)/g!$, this is the $g$-fold self intersection number of $D$.

**Theorem 1.8.6 Vanishing.** If $\#K(L) < \infty$ then there is a unique integer $0 \leq i(L) \leq g$ with $H^i(A, L) \neq 0$ and $H^p(A, L) = 0$ for all $p \neq i$. Moreover $i(L^{-1}) = g - i(L)$.

Recall Subsection 1.5.3: So for ample $L$ we have $K(L)$ finite, so the vanishing theorem applies. Additionally for very ample $L$ we know $H^0(A, L) \neq 0$ so in this case we get vanishing of higher cohomology.

**Theorem 1.8.7 Finiteness.** Let $k$ be a finite field, and $g, d \geq 1$ integers. Up to isomorphism there are only finitely many abelian varieties $A/k$ of dimension $g$ and with a polarization of degree $d^2$.

**Proof.** (Super sketch) Over a finite field implies there is an ample $L$ with $\lambda_L$ a polarization of degree $d^2$, then using above $\chi(L^3) = 3^g d$ and $L^3$ is very ample hence $\dim H^0(A, L^3) = 3^g d$ so we get an embedding into $\mathbb{P}^{3^g d - 1}$.

The degree of $A$ in $\mathbb{P}^{3^g d - 1}$ is $((3D)^g) = 3^g d (g!)$ . It is determined by its Chow form, which by these formulae has some (large) bounded degree, as we are over a finite field however there are only finitely many such. ■
1.8.2 Étale Cohomology of Abelian Varieties

See [65] or [83].

Recall for abelian varieties over $A/\mathbb{C}$ we considered singular cohomology of the complex points $A(\mathbb{C})$. Indeed this theory was strongly connected to the lattice $\Lambda$ defining $A(\mathbb{C})$.

We saw that in fact $\pi_1(A, 0) = \pi^{-1}(0) = \Lambda \subseteq V$ which was the universal covering space of $A(\mathbb{C})$. We want to emulate this over a general field.

We want to allow multiplication by $n$ to define finite covers for our abelian varieties as they did before.

Problem: Zariski topology is too coarse: we can’t find an open $U$ set around $0 \in A$ such that $[2]: U \to A$ is an isomorphism onto its image. Isogenies are not local isomorphisms for the Zariski topology.

How on earth do we “allow” maps which are clearly not local isomorphisms to become such? First what do we mean by local isomorphism?

$$
\begin{array}{ccc}
 f^{-1}(U) & \xrightarrow{i} & U \\
 U & \downarrow & \\
 X & \xrightarrow{f} & Y
\end{array}
$$

There exists an open subset $U$ such that the base change $X \times_Y U$ is isomorphic with $\bigsqcup U$ of several copies of $U$ in a compatible way with the map to $U$.

So let’s cheat, the best isomorphism is the identity map

$$
\begin{array}{ccc}
 X & \xrightarrow{i} & X \\
 X & \downarrow & \\
 X & \xrightarrow{f} & Y
\end{array}
$$

if we define an “open set” $U$ to be a morphism $X \to Y$ with the properties we want, then all such become local isomorphisms.

By taking our topology to be given by some maps we decide are decent covering maps we can circumvent these difficulties.

What is the correct class of morphisms to take here, we feel like our $[n]$ maps should count. Taking inspiration from differential geometry perhaps, we are led to the notion of a local diffeomorphism, an étale map.

**Definition 1.8.8** Let $X, Y$ be nonsingular varieties over $k = \bar{k}$. Then $f : X \to Y$ is étale at a point $P \in X$ if

$$
df : \text{Tgt}_p(X) \to \text{Tgt}_{f(P)}(Y)
$$

is an isomorphism.

**Proposition 1.8.9** Let $f : A^m \to A^m$ then $f$ is étale at $(a_1, \cdots, a_m)$ iff

$$
\left( \frac{\partial(X_i \circ f)}{\partial Y_j} \big|_{(a_i)} \right)
$$

is nonsingular.

**Example 1.8.10** A non-étale map. Consider the map

$$
A^2 \to A^2
$$
we can see that the image of \( y = 0 \) is the nodal cubic \( (Y^3 = X^2) \), which is messed up (singular) at \((0,0)\). The jacobian is

\[
\begin{pmatrix}
3x^2 & 0 \\
2x & 1
\end{pmatrix}
\]

so this matrix is singular exactly when \( x = 0 \) (unless characteristic 3). So the map is not étale at these points. \(\square\)

**Proposition 1.8.11** The maps \( \left[ n \right] \) are étale on an abelian variety \( A/k \) for all \( \text{char } k \nmid n \)

**Proof.** Key point \( d(\alpha + \beta) = (d\alpha)_0 + (d\beta)_0 \). So the map on tangent spaces is simply multiplication by \( n \). \(\blacksquare\)

**Definition 1.8.12 Étale morphisms.** A morphism \( f : X \to Y \) of schemes is étale if it is flat and unramified.

Flatness for finite morphisms of varieties is equivalent to each fibre \( f^{-1}(t) \) being of equal cardinality, counting multiplicities.

All isogenies are finite and flat.

**Definition 1.8.13** Let \( \text{FEt}/X \) be the category of finite étale maps \( \pi : Y \to X \) (i.e. finite étale coverings of \( X \)).

Then after picking a basepoint \( x \in X \) we can map

\[
F : \text{FEt}/X \to \text{Set}
\]

\[
\pi \mapsto \text{Hom}_X(x, Y) \cong \pi^{-1}(x).
\]

This is in fact pro-representable, i.e. there exists a system

\[
\tilde{X} = (X_i)_{i \in I}
\]

with

\[
F(Y) = \text{Hom}(\tilde{X}, Y) = \lim_{i \to} \text{Hom}(X_i, Y).
\]

We then define

\[
\pi_1(X, x) = \text{Aut}_X(\tilde{X}) = \lim_{i \to} \text{Aut}_X(X_i).
\]

So we need to understand étale covers of abelian varieties. Following [87]:

**Proposition 1.8.14** surprising proposition. Let \( X \) be a complete variety over a field \( k \) with \( e \in X(k) \) and \( m : X \times X \to X \) s.t. \( m(e, x) = m(x, e) = x \) for all \( x \in X \). Then \( (X, m, e) \) is an abelian variety.

**Proof.** (Sketch)

Let

\[
\tau : X \times X \to X \times X
\]

\[
\tau(x, y) = (xy, y)
\]

so \( \tau^{-1}(e, e) = (e, e) \). Some exercise in Hartshorne implies \( \text{im } \tau \) has dimension \( 2 \dim X \).

Reduce to algebraically closed case.

Let

\[
\tau^{-1}(\{e\} \times X) = \{(x, y) : xy = e\} = \Gamma \subseteq X \times X.
\]
as $\tau$ is surjective we get $p_2: \Gamma \to X$ is also so pick an irreducible $\Gamma_1 \subseteq \Gamma$ with $p_2(\Gamma_1) = X$. This also implies $p_1(\Gamma_1) = X$.

Let
\[
f: \Gamma_1 \times X \times X \to X
f((x, y), z, w) = x((yz)w)
\]
then
\[
f(\Gamma_1 \times \{e\} \times \{e\}) = \{\text{eee} = \{e\}
\]
so a version of rigidity 1.1.11 gives
\[
x((yz)w) = zw \quad \forall (x, y) \in \Gamma_1, \ z, w \in X
\]
So letting $w = e$ we get
\[
x(yz) = z.
\]
Fix $y \in X(k)$, and then by surjectivity we can find $x, z \in X(k)$ with $(x, y) \in \Gamma_1 \ni (y, z)$. So we get
\[
x = x(yz) = ze = z
\]
and so $y$ has both a left and right inverse. We then multiply above by $y$ to get
\[
y(zw) = y(x((yz)w)) = (yz)w
\]
so $X(k)$ is associative.

**Theorem 1.8.15 Lang-Serre.** Let $X/k$ be an abelian variety and $Y/k$ a variety with $e_Y \in Y(k)$ s.t. $f: Y \to X$ is an étale covering where $f(e_Y) = e_X$. Then $Y$ can be given the structure of an abelian variety so that $f$ is a separable isogeny.

**Proof.** Must construct a group law on $Y$:

Take the graph of $m: X \times X \to X$
\[
\Gamma_X \subseteq X \times X \times X
\]
and pullback along $f \times f \times f$ to
\[
\Gamma'_Y \subseteq Y \times Y \times Y
\]
fix the connected component $\Gamma_Y$ containing $(e_Y, e_Y, e_Y)$.

Call the projections from $\Gamma_Y q_1$. Now we must show that $q_{12}: \Gamma_Y \to Y \times Y$ is an isomorphism, then $m_Y: Y \times Y \to Y$ can be defined as $q_3 \circ q_{12}^{-1}$. $q_{12}$ has sections $s_1, s_2$ over $\{e_Y\} \times Y, Y \times \{e_Y\}$ respectively given by $s_1(e_Y, y) = (e_Y, y, y)$ and $s_2(y, e_Y, y) = (y, e_Y, y)$. So $m_Y$ satisfies the conditions of the surprising proposition.

\[
\begin{array}{ccc}
\Gamma_Y & \xrightarrow{q_{12}} & \Gamma_X \\
\downarrow & \searrow & \downarrow p_{12} \\
Y \times Y & \xrightarrow{f \times f} & X \times X
\end{array}
\]

the horizontal maps are étale coverings and the rightmost an isomorphism so $q_{12}$ is an étale covering. The projection $p_2 \circ q_{12} = q_2: \Gamma_Y \to Y$ is smooth proper. Fact: all fibres of $q_2$ are irreducible. So $Z = q_{12}^{-1}(e_Y) = q_{12}^{-1}(Y \times \{e_Y\})$ is irreducible. Moreover $q_{12}$ restricts to an étale covering $Z \to Y = Y \times \{e_Y\}$ of the same degree, but $s_2$ is a section of this covering, hence it is an isomorphism. Hence $q_{12}$ has degree 1 and is therefore an isomorphism as required.

So we have some control over the finite étale maps, what does the covering space look like? Last week we saw that for an isogeny $\alpha: B \to A$ we could find
\( \beta : A \to B \) with \( \beta \circ \alpha = [n] : A \to A \). This means we can take our universal covering space to be 
\[(A)_{\epsilon i} \]
with multiplication by \( n \) maps.
So we find
\[
\pi_1^{et}(A,0) = \lim_{\text{homotopy}} \text{Aut}_A(A \to A[n]) = \lim_{\text{homotopy}} A[n].
\]

**Theorem 1.8.16**

\[ H^1_{et}(A,\mathbb{Z}_l) = \text{Hom}(\pi_1(A,0),\mathbb{Z}_l) = \text{Hom}(T_1,\mathbb{Z}_l) \]

**Theorem 1.8.17**

\[ H'(A_{\text{et}},\mathbb{Z}_l) = \bigcap_{r} H^1(A_{\text{et}},\mathbb{Z}_l) \]

Note that Milne gives a combined proof of the above two statements, this relies on some theorems on Hopf algebras such as [23, Theoreme 6.1].

### 1.9 Weil pairings (Maria)

#### 1.9.1 Weil pairings on elliptic curves

Start with elliptic curves, later repeat for abelian varieties. \( E/k \) an elliptic curve, \( m \geq 2 \), if \( \text{char}(k) = p > 0 \) \( (m,p) = 1 \). The Weil \( e_m \)-pairing \( e_m : E[m] \times E[m] \to \mu_m \) is defined as follows: Fix \( T \in E[m] \) then \( f \in \tilde{k}(E) \) s.t. \( \text{div}(f) = m(T) - m(0) \).

Fix \( T' \in E \) with \( mT' = T \) and \( g \in \tilde{k}(E) \) s.t. \( \text{div}(g) = [m]'(T) = [m]'(0) = \sum_{R \in E[m]} (T + R) - (R) \). Check \( \text{div}(f \circ [m]) = \text{div}(g^m) \), hence

\[ f \circ [m] = c g^m \]

so can assume \( f \circ [m] = g^m \). For \( s \in E[m], x \in E: \)

\[ g(x + s) = f([m]x + [m]s) = f([m]x) = g(x)^m \]

\[ \frac{g(\cdot + s)^m}{g(\cdot)} : E \to \mathbb{P}^1 \]

is then a constant function, since not surjective. So we define

\[ e_m : E[m] \times E[m] \to \mu_m \]

\[ (s,t) \mapsto \frac{g_t(x + s)}{g_t(x)} \]

will state many properties later, but for now. \( e_m \) is compatible:

\[ e_{mm'}(a,a')^{m'} = e_m(m'a, m'a') \forall a,a' \in E[m'm'] \]

so for any \( l \neq \text{char}(k) \) prime we can combine \( e_{m'} \)-pairings into an \( l \)-adic Weil pairing on \( T_lE \)

\[ e : T_lE \times T_lE \to T_l\mu = \mathbb{Z}_l(1) \]
1.9.2 Weil pairings on abelian varieties

Story will be broadly similar to before but we must use the dual, which doesn’t appear in the presentation for elliptic curves.

Let $A/k$ be an abelian variety $k = \bar{k}$. We construct a Weil $e_m$-pairing

$$e_m: A[m] \times A^\vee[m] \to \mu_m$$

$$(a, a') \mapsto \frac{g \circ t_a(x)}{g(x)} = \frac{g(x + a)}{g(x)}$$

Fix $a \in A[m], a' \in A^\vee[m]$ say $a'$ corresponds to $L$ and a divisor $D$ then $L^m$ and $m^*_A L$ are trivial so $\exists f, g \in k(A)$ s.t.

$$\text{div}(f) = mD$$
$$\text{div}(g) = m^*_A D$$

again we have

$$\text{div}(f \circ m_A) = \text{div}(g^m)$$
$$g(x + a)^m = g(x)^m$$

**Proposition 1.9.1** The Weil $e_m$-pairing has the following properties

1. $e_m$ is bilinear

   $$e_m(a_1 + a_2, a') = e_m(a_1, a')e_m(a_2, a')$$

   $$e_m(a, a'_1 + a'_2) = e_m(a, a'_1)e_m(a, a'_2)$$

2. $e_m$ is non-degenerate: if $e_m(a, a') = 1 \forall a \in A[m]$ then $a' = 0$ (and likewise for the reverse).

3. $e_m$ is Galois-invariant... but we assume $\bar{k} = k$ so we ignore this.

4. $e_m$ is compatible

   $$e_{mm'}(a, a')^{m''} = e_m(m'a, m'a') \forall a \in A[mm'], a' \in A^\vee[mm']$$

   $$(mm', \text{char } k) = 1$$

**Corollary 1.9.2** There exists a bilinear non-degenerate (Galois invariant) pairing

$$e_l = e: T_l A \times T_l A^\vee \to T_l \mu$$

$$((a_n), (a'_n)) \mapsto (e_{l^n}(a, a'_n))$$

For a homomorphism $\lambda: A \to A^\vee$ we define

$$e_{\lambda}^l: A[m] \times A[m] \to \mu_m$$

$$(a, a') \mapsto e_m(a, \lambda(a'))$$

$$e_l: T_l A \times T_l A \to T_l \mu$$

$$(a, a') \mapsto e_m(a, \lambda(a')).$$

**Notation.** If $\lambda = \lambda L e L = e_{\lambda L}.$

**Proposition 1.9.3** For a homomorphism $\alpha: A \to B$

1. $e(\alpha, \alpha^\vee(b)) = e(\alpha(a), b) \forall a \in T_l A, b \in T_l B$
2. \( e^{\alpha \cdot \lambda} (a, a') = e^\lambda (a(a), a(a')) \)
   for \( a, a' \in T_1(A) \), \( \lambda \in \text{Hom}(B, B^\vee) \).

3. \( e^{\alpha \cdot L} (a, a') = e^L (a(a), a(a')) \)
   \( a, a' \in T_1 A, L \in \text{Pic}(B) \).

4. \( \text{Pic} A \rightarrow \text{Hom}(\bigwedge^2 T_1 A, T_1 \mu) \)

is a homomorphism (in particular \( e^L \) is skew-symmetric).

Proof.

1. \( a = (a_n) \in T_1 A, b = (b_n) \in T_1 B^\vee \) fix a divisor \( D \) on \( B \) representing \( b_n \) and \( g \in k(B) \) s.t. \( \text{div}(h) = (l_B^n)^n D \). Then \( a^* D \) represents \( \alpha^\vee (b_n) \) so:

\[
\text{div}(g \circ \alpha) = \alpha^* \text{div}(g) = a^* (l_B^n)^n D = (l_A^n)^n a^* D.
\]

So

2. \( e^{\alpha \cdot \lambda} (a, a') = e(a, \alpha^\vee \lambda a(a')) = e(a(a), \lambda (a(a'))) = e^\lambda (a(a), a(a')). \)

3. \( \lambda_{a'} \cdot L = \alpha^\vee \lambda_L \alpha \)

4. Follows from \( \lambda_L \otimes L' = \lambda_L + \lambda_L' \).

Example 1.9.4 Computation over \( \mathbb{C} \). \( A / \mathbb{C} \) be an abelian variety

\[
0 \rightarrow \mathbb{Z} \rightarrow \mathcal{O}_A \overset{e^{2\pi i}}{\longrightarrow} \mathcal{O}^\times \rightarrow 0
\]

induces

\[
H^1(A(\mathbb{C}), \mathbb{Z}) \rightarrow H^1(A(\mathbb{C}), \mathcal{O}) \rightarrow H^1(A(\mathbb{C}), \mathcal{O}^\times) \cong \text{Pic} A \rightarrow H^2(A(\mathbb{C}), \mathbb{Z})
\]

and

\[
H^1(A(\mathbb{C}), \mathcal{O}) / H^1(A(\mathbb{C}), \mathbb{Z}) \cong A^\vee(\mathbb{C}) = \text{Pic}^0(A)
\]

so we get an exact sequence

\[
0 \rightarrow \text{NS}(A) \rightarrow H^2(A(\mathbb{C}), \mathbb{Z}) \rightarrow H^2(A(\mathbb{C}), \mathcal{O}_A)
\]

\[
\lambda \mapsto E_\lambda
\]

then we can regard \( E_\lambda \) as a skew-symmetric 2-form on \( H_1(A(\mathbb{C}), \mathbb{Z}) \). Mumford pg. 237 proves

\[
\begin{array}{c}
H_1(A(\mathbb{C}), \mathbb{Z}) \times H_1(A(\mathbb{C}), \mathbb{Z}) \rightarrow \mathbb{Z} \ni m \\
\downarrow \\
T_1 \times T_1 \rightarrow T_1 \mu \ni \zeta^m
\end{array}
\]

commutes with - sign so \( e^\lambda (a, a') = \zeta^{-E(\alpha(a'))} \) \( \square \)
1.9.3 Results about polarizations

Let \( \lambda \) be a skew-symmetric form on \( A \times A' \) for all \( \lambda \in NS(A) \) then \( \lambda = \alpha' \lambda' \) for \( \lambda' \in NS(B) \) \( \iff \forall l \deg(\alpha) l \) prime there exists a skew-symmetric form \( f : T_1B \times T_1B \to T_1\mu \) s.t. \( e^\lambda(a,a') = f(\alpha(a),\alpha(a')) \) for all \( a,a' \in T_1(A) \).

**Proposition 1.9.11** Assume \( \alpha : A \to B \) is an isogeny of degree prime to \( \text{char} k \) and \( \lambda \in NS(A) \) is skew-symmetric, define \( L \) as the Poincaré sheaf on \( A \times A' \) and \( L' \) as the sheaf on \( B \times B' \) for some \( \lambda \in \text{Pic } A \) iff \( e^\lambda \) is skew-symmetric.

**Proof.** Clear.

**Corollary 1.9.6** Assume \( \lambda \in NS(A) \) is divisible by \( l^n \) \( \iff e^\lambda \) is divisible by \( l^n \) in \( \text{Hom}(A^{\lambda}, B^{\lambda}) \).

**Proof.** Apply theorem 13.4 with \( \lambda = l^n \).

**Lemma 1.9.7** Let \( P \) be the Poincaré sheaf on \( A \times A' \) then \( e^P((a,b),(a',b')) = \frac{e(a,b')}{e(a',b)} \) for all \( a,a' \in T_1A, b,b' \in T_1A' \).

**Proof.** Milne 1986 16.7. Use:

\[
(1 + \lambda \chi)^* P \cong m^* \lambda \chi^* L^{-1} \otimes q^* L^{-1}
\]

**Proposition 1.9.8** Assume \( \lambda \neq 1,2 \) then a homomorphism \( \lambda : A \to A' \) is \( \lambda = \lambda \chi \) for some \( \lambda \in \text{Pic } A \) iff \( e^\lambda \) is skew-symmetric.

**Proof.** Note 1.9.10. \( e^\lambda \) is skew-symmetric.

**Definition 1.9.9** For a polarization \( \lambda : A \to A' \) define \( e^\lambda : \ker(\lambda) \times \ker(\lambda) \to \mu_m \)

\[
(a,a') \mapsto e_m(\alpha(a),\lambda(b))
\]

where \( m \) kills \( \ker(\lambda) \) and \( b \in A \) s.t. \( mb = a' \).

**Check:** this is well defined.

**Note 1.9.10** \( e^\lambda \) is skew-symmetric.

**Proposition 1.9.11** Assume \( \alpha : A \to B \) is an isogeny of degree prime to \( p, \lambda : A \to A' \) polarization then \( \lambda = \alpha' \lambda' \), \( \lambda' : B \to B' \) polarization iff

\[
\ker(\alpha) \subset \ker \lambda
\]

\( e^\lambda \) is trivial on \( \ker(\alpha) \times \ker(\alpha) \)
Note 1.9.12 If \( \lambda = \alpha^* \lambda' \) then

\[
\deg(\lambda) = \deg(\lambda') \deg(\alpha)^2.
\]

Corollary 1.9.13 13.10. An abelian variety, \( \lambda: A \to A^\vee \) is a polarization with \((\deg(\lambda), p) = 1 \) then \( A \) is isogenous to a principally polarized abelian variety.

Proof. Fix \( l \) \( \deg(\lambda) \) prime. Choose a subgroup \( N \subseteq \ker \lambda \) of order \( l \) let \( \alpha: A \to A/N = B \) \( N \) is cyclic and \( e^\lambda \) is skew-symmetric so \( e^\lambda \) is trivial on \( N \times N \) so \( B \) has a polarization of degree \( \deg(\lambda)/l^2 \) by 13.8. \( \Box \)

Corollary 1.9.14 13.11. Let \( \lambda \) be a polarization of \( A \) s.t. \( \ker(\lambda) \subseteq A[m] \) for some \((m, p) = 1 \). If \( \exists \alpha: A \to A \) s.t. \( \alpha(\ker(\lambda)) \subseteq \ker(\lambda) \) and \( \alpha^* \lambda = -\lambda \) on \( A[m^2] \) then \( A \times A^\vee \) is principally polarized.

Theorem 1.9.15 13.12 (Zarhin’s trick). For any abelian variety \( A \) \((A \times A^\vee)^4 \) is principally polarized.

Proof. Fix \( \lambda: A \to A^\vee \) polarization, assume \( \ker(\lambda) \subseteq A[m] \) \((m, p) = 1 \) there exists \( a, b, c, d \in \mathbb{Z} \) s.t. \( a^2 + b^2 + c^2 + d^2 = m^2 - 1 = -1 \) (mod \( m^2 \)) then

\[
\begin{pmatrix}
a & -b & -c & -d \\
b & a & d & -c \\
c & -d & a & b \\
d & c & -b & a
\end{pmatrix}
\]

works. \( \Box \)

Corollary 1.9.16 13.13. Let \( k \) be a finite field, then for each \( g \in \mathbb{Z} \) there exist only finitely many isomorphism classes of abelian varieties of dimension \( g \) over \( k \).

Proof. \( A/k \) an abelian variety of dimension \( g \), so \((A \times A^\vee)^4 \) is an abelian variety of dimension \( 8g \) with a principal polarization so using theorem 11.2 there are finitely many (up to \( \cong \)) of those. Also \((A \times A^\vee)^4 \) has finitely many direct factors (theorem 15.3). \( \Box \)

1.10 The Rosati involution (Alex)

Let \( A/k \) be an abelian variety and \( f \in \text{End}(A) \). Via pullback we get \( \hat{f} \in \text{End}(\hat{A}) \), in the case where \( A \) is polarized i.e. we have an isogeny \( \phi: A \to \hat{A} \) we might wonder what the relation is between \( f \) and \( \hat{f} \). E.g. \( \text{id} = \text{id} \) but here we have \( \hat{\phi} \text{id} \phi = [\deg \phi] \), this is a little ugly, depends on the degree of our polarization.

If we work with \( \text{Hom}^0(A, B) = \text{Hom}(A, B) \otimes \mathbb{Q} \) rather than \( \text{Hom}(A, B) \) we have a bona fide inverse \( \phi^{-1} \) of an isogeny \( \phi \). So now we can ask precisely, what is the relationship of the endomorphism \( f^\dagger = \phi^{-1} \circ \hat{f} \circ \phi \in \text{End}^0(A) \) with \( f \)?

What sort of properties does this map \( f \mapsto f^\dagger \) have?

Definition 1.10.1 The Rosati involution. The map \( \phi^{-1} \circ \hat{\phi} = -\dagger: \text{End}^0(A) \to \text{End}^0(A) \) is called the Rosati involution. \( \diamond \)

Proposition 1.10.2 \( -\dagger \) is \( \mathbb{Q} \)-linear

Proposition 1.10.3 \( -\dagger \) is an anti-homomorphism i.e.

\[
(fg)^\dagger = g^\dagger f^\dagger
\]

Proposition 1.10.4 Recall the \( l \)-adic Weil pairing for \( l \neq \text{char}(k) \), fix \( a, a' \in V_1A = T_1A \otimes \mathbb{Q} \), then

\[
e^0_l(fa, a') = e^0_l(a, f^\dagger a').
\]
CHAPTER 1. ABELIAN VARIETIES

Proof.

\[ e_i^0(fa, a') = e_i(fa, \phi a') = e_i(a, f\phi a') = e_i(a, \phi \phi^{-1} f\phi a') = e_i^0(a, f^4 a') \]

Proposition 1.10.5 \( ^{-1} \) is an involution, i.e.

\[ \alpha^{\ddagger} = \alpha. \]

Proof. We apply the previous proposition and skew-symmetry of a polarization (over some extension)

\[ e_i^1(\alpha a, a') = e_i^1(a, \alpha^{\ddagger} a') = e_i^1(\alpha^{\ddagger} a, a') \]

for all \( a, a' \in V_i A \).

Proposition 1.10.6 This is positive definite. In fact

\[ \text{tr}(ff^\ddagger) = 2g(Dg - 1 \cdot f^*(D)) \]

for \( \phi = \phi_{L(D)} \).

So we have a weird algebra with a weird operation, what can we do? Perhaps inspired by the killing form of a Lie algebra:

We can form a bilinear form using the trace

\[ \text{End}^0(A) \times \text{End}^0(A) \to \mathbb{Q} \]

\[ (f, g) \mapsto \text{tr}(fg^\ddagger). \]

Proposition 1.10.6 This is positive definite. In fact

\[ \text{tr}(ff^\ddagger) = 2g(Dg - 1 \cdot f^*(D)) \]

for \( \phi = \phi_{L(D)} \).

So given a simple abelian variety we have a division algebra \( / \mathbb{Q} \) equipped with a positive definite involution.

Definition 1.10.7 Albert algebras? A division algebra \( D \) finite over \( \mathbb{Q} \) with an involution \( ' \) such that \( \text{tr}_{D/\mathbb{Q}}(xx') > 0 \ \forall x \in D^\times \) is called an Albert algebra.

Such algebras were studied by Albert who proved an important classification theorem.

Theorem 1.10.8 Albert (1934/5). Let \( (D, ' ) \) be an Albert algebra, let \( K \) be the center of \( D \) and \( K_0 \) the subfield fixed by \( ' \). Then we have the following classification

1. Type I: \( D = K = K_0 \) a totally real number field and \( ' \) is the identity.

2. Type II: \( D \) is a quaternion algebra over \( K = K_0 \) a totally real field, that is split at all infinite places and \( ' \) is defined by letting starting with the standard quaternion algebra conjugation for which \( x + x' = \text{tr}(x) \) and then letting \( x' = ax^*a^{-1} \) for some \( a \in D \) for which \( a^2 \in K \) and is totally negative.

3. Type III: \( D \) is a quaternion algebra over \( K = K_0 \) a totally real field, that is ramified at all infinite places and \( ' \) is the standard quaternion algebra conjugation as above.

4. Type IV: \( D \) is a division algebra over a CM field \( K \) and \( K_0 \) is the maximal totally real subfield. Additionally if \( v \) is a finite place with \( v = \bar{v} \) we have \( \text{Inv}_v(D) = 0 \) and \( \text{Inv}_{\bar{v}}(D) + \text{Inv}_v(D) = 0 \) for all places \( v \).

There is a fascinating table in Mumford, page 200 or something.

As one might hope, changing the polarization does not change the type of the algebra + involution pair.

One might wonder which endomorphisms are invariant under this process? I.e. what is

\[ \{ f \in \text{End}^0(A) : f^\ddagger = f \}. \]
Equivalently, for which \( f \) is the dual given by conjugating by our polarization. We can map

\[
\mathbb{Q} \otimes \mathbb{Z} \text{NS}(X) = \mathbb{Q} \otimes \mathbb{Z} \text{Pic} X / \text{Pic}^0 X \to \text{Hom}(A, \hat{A})
\]

\( \mathcal{M} \mapsto \phi_{\mathcal{M}} \)

however we also have an isomorphism

\[
\text{Hom}^0(A, \hat{A}) \sim \to \text{End}^0(A)
\]

\( \phi \mapsto \lambda^{-1} \phi \)

for some fixed polarization \( \lambda \), hence we can view \( \text{NS}(A) \otimes \mathbb{Q} \) inside \( \text{End}^0(A) \).

**Proposition 1.10.9** Assume \( k \) algebraically closed. The image of

\[
\mathbb{Q} \otimes \mathbb{Z} \text{NS}(X) \to \text{End}^0(A)
\]

is the fixed subspace

\[
\{ f \in \text{End}^0(A) : f^\dagger = f \}.
\]

**Proof.** Fix \( \alpha \in \text{End}^0(A) \) and \( l \neq \text{char}(k) \) odd. Applying Proposition 1.9.8 we see that \( \lambda \alpha = \phi_{\mathcal{L}} \) for some \( \mathcal{L} \) iff \( e^\lambda_\alpha \) is skew-symmetric, but we also have

\[
e^\lambda_\alpha (a, a') = e^\lambda_\alpha (a, \alpha a') = -e^\lambda_\alpha (\alpha a', a) = -e_\alpha (a', \hat{\alpha} \lambda a)
\]

for all \( a, a' \in V_lA \) this is the same as requiring \( \lambda \alpha = \hat{\alpha} \lambda \) i.e. \( \alpha = \alpha^\dagger \). 

Another cool result we can now prove (in fact this was the reason Weil introduced the notion of a polarization).

**Theorem 1.10.10** The automorphism group of a polarized abelian variety is finite.

**Proof.** Let \( \alpha \) be an automorphism of \((A, \lambda)\) i.e. \( \lambda = \hat{\alpha} \lambda \alpha \), then \( \alpha^\dagger \alpha = 1 \) and so

\[
\alpha \in \text{End}(A) \cap \{ \beta \in \text{End}(A) \otimes \mathbb{R} : \text{Tr}(\alpha^\dagger \alpha) = 2g \}
\]

but \( \text{End}(A) \) is discrete inside the compact RHS.

---

**1.11 Abelian Varieties over finite fields (Ricky)**

Set \( q = p^m \), \( p \) prime. Given \( X / \mathbb{F}_q \) have geometric Frobenius \( \pi_X : X \to X \) which acts as id on \( |X| \) and sends \( f \to f^q \) for \( f \in \mathcal{O}_X(U) \).

**Example 1.11.1** \( X \hookrightarrow \mathbb{P}^n \) then \( \pi_X(a_0 : \cdots : a_n) = (a_0^q : \cdots : a_n^q) \). 

We also have absolute Frobenius

\[
F : X \to X^{(p)}.
\]

**Example 1.11.2**

\[
X : y^2 = x^3 + i / \mathbb{F}_q
\]

\[
X^{(p)} : y^2 = x^3 + i^3 = x^3 - i / \mathbb{F}_q
\]

\[ \square \]
We see that $X^{(p^n)} = X$ and $F^m = \pi_X$.

If $f : X \to Y$ of $F_q$-schemes then $\pi_Y \circ f = f \circ \pi_X$. Now let $X$ be an abelian variety over $F_q$. From above, we have $\pi_X$ commutes with all elements of $\text{End}^0(X) = \text{End}^0(X) \otimes \mathbb{Q}$. Let $f_X$ be the characteristic polynomial of $T_l(\pi_X) : V_l(X) \to V_l(X)$ for $l \neq p$.

An alternative definition is to take $f_X \in \mathbb{Z}[X]$ monic of degree $2g$, $g = \dim X$ s.t.

\[ f_X(n) = \deg([n] - \pi_X), \]

see 12.8.

**Proposition 1.11.3** 16.3. Assume $X$ is elementary, (i.e. its isogenous to $A^n$ for some $A$ simple). Then $\mathbb{Q}[\pi_X] \subseteq \text{End}^0(X)$ is a field and $f_X$ is a power of the minimal polynomial of $\pi_X$ over $\mathbb{Q}$.

**Proof.** Since $X$ is elementary $\mathbb{Z}(\text{End}^0(X))$ is a field containing $\mathbb{Q}[\pi_X]$. Let $g$ be the minimal polynomial of $\pi_X$ over $\mathbb{Q}$.

Let $\alpha$ be a root of $f_X$. Then $g(\alpha)$ is an eigenvalue of $g(V_l(\pi_X)) = V_l(g(\pi_X)) = V_l(0) = 0$. Hence $g(\alpha) = 0$.

**Theorem 1.11.4** 16.4. Let $g = \dim(X)$.

1. Every root of $f_X \alpha \in \mathbb{C}$ satisfies $|\alpha| = q^{1/2}$.

2. If $\alpha$ is a root of $f_X$, then $\bar{\alpha}$ with the same multiplicity. In particular if $\alpha = \pm \sqrt{q}$ then it occurs with even multiplicity.

We need some facts before proving this: Ref 5.20, 5.21

- There exists $V : X^{(p)} \to X$

such that $V \circ F = [p]_X$ and $F \circ V = [p]_{X^{(p)}}$.

Using $\deg F = p^g$ get $\deg V = p^g$.

- By induction $[p^m] = V^m \circ F^m$.

We also need some facts about $F$ and $V$ relative to $X^\vee$.

\[ F^\vee_X = V_{X^\vee} : (X^{\vee})^{(p)} \to X^{\vee} \]

identifying $(X^{\vee})^{(p)} = (X^{(p)})^\vee$, Ref 7.33, 7.34.

**Proof.** Reduce to the case where $X$ is simple, we have $h : X \to X_1 \times X_2 \times \cdots \times X_s$
an isogeny with $X$, simple, then $h$ induces an isomorphism
\[ h: V_l(X) \cong \bigoplus_i V_l(X_i) \]
so $f_X = f_{X_1} \cdots f_{X_i}$. Hence we can assume $X$ is simple.

Let $\lambda: X \to X^*$ be a polarization of $X$ and $\dagger$ be the corresponding Rosati involution on $\text{End}^0(X)$ we will show that $\pi_X \pi_X^\dagger = q$.

\[ \pi_X \pi_X^\dagger = \pi_X \lambda^{-1} \pi_X^\dagger \lambda = \lambda^{-1} \pi_X^\dagger \pi_X^\dagger \lambda = \lambda^{-1}[q] \lambda = [q] \]

To see $\pi_X^\dagger = \pi_X = q$ we use $\pi_X = F^m$ and $\pi_X^\dagger = V^m$. So $\pi_X^\dagger \pi_X^\dagger = F^m V^m = p^m = q$. As $X$ is simple $\mathbb{Q}[\pi_X]$ is a field. Thus $f_X$ is a power of $g$, the minimal polynomial of $\pi_X / \mathbb{Q}$. So the complex roots of $f_X$ are $i(\pi_X)$ for every embedding $\mathbb{Q}[\pi_X] \hookrightarrow \mathbb{C}$. Since $\pi_X^\dagger = q/\pi_X$, we see that

\[ \mathbb{Q}[\pi_X] \subseteq \text{End}^0(X) \]
is stable under $\dagger$. We have two cases for such a $K = \mathbb{Q}[\pi_X]$

1. $K$ is totally real and $\dagger = \text{id}$.
2. $K$ is a CM field and $\dagger = \tilde{\cdot}$.

hence we get

\[ i(\pi_X \pi_X^\dagger) = i(\pi_X) i(\pi_X) = q \]

for any $i: K \to \mathbb{C}$.

If $\pm \sqrt{q}$ is a root of $f_X$ then we are in the case of $K$ totally real. If $\sqrt{q}$ has multiplicity $n$. Then $-\sqrt{q}$ has multiplicity $2g - n$. Thus $f_X(0) = (-1)^n q^g$. But also $f_X(0) = \deg(0 - \pi_X) = q^g$. Hence $n$ is even.

Honda-Tate. The correspondence between isogeny classes of $X / \mathbb{F}_q$ and conjugacy classes of $q$-Weil numbers is a bijection. (i.e. algebraic integers $\alpha$ s.t. $|\alpha| = \sqrt{q}$ for all $i: \mathbb{Q}(\alpha) \hookrightarrow \mathbb{C}$).

Using relations between a curve $C / \mathbb{F}_q$ and its Jacobian $J(C)$, one can show:

**Theorem 1.11.5** Hasse-Weil-Serre bound.

\[ q + 1 - g [2 \sqrt{q}] \leq \# C(\mathbb{F}_q) \leq q + 1 + g [2 \sqrt{q}] \]

where $g = g(C)$.

**Proof.** Hint: Use Lefschetz trace and $H^1(C, \mathbb{Q}_l) \approx H^1(J(C), \mathbb{Q}_l)$.

Application: Let $f = J_0(103) = J(X_0(103))$. $J \sim J_+ \times J_-$.

\[ f = \text{id}(w \pm \text{id}) \]

are Atkin-Lehner. $\dim J = 8$ and $\dim(J_-) = 6$. In fact $\exists f \in S_2(\Gamma_0(103))$ an eigenform s.t. if

\[ f = \sum_{n \geq 1} a_n q^n \]

then $[\mathbb{Q}(a_n)_{n \geq 1} : \mathbb{Q}] = 6$ and $\text{tr}(F_{l,p}\cdot T_l(J_-)) = \text{tr}_{\mathbb{Q}(a_p)}$ for $l \not= p, p \not= 103$ We can compute $\text{tr}_{\mathbb{Q}(a_2)} = 4$. This implies that $J_- \times F_2$ is not the Jacobian of a curve $/F_2$, if it were, then if $J_- \times F_2 = J(C)$ then via Lefschetz trace formula

\[ \# C(F_2) = 2 + 1 - 4 = -1 \]

similar thing at 17.
1.12 Tate’s Isogeny Theorem (Sachi)

1.12.1 The Theorem

**Theorem 1.12.1 Tate.** Let \(A, B/F_q = k, q = p^n, l \neq p\) be abelian varieties and \(G = \text{Gal}(k^{1/k})\), then

\[
\text{Hom}_k(A, B) \otimes \mathbb{Z}/l \to \text{Hom}_G(T_k A, T_k B) = \text{Hom}_{\mathbb{Z}/l}(T_k A, T_k B)^G
\]

(where the \(G\) action on \(\text{Hom}_{\mathbb{Z}/l}(T_k A, T_k B)\) is \((gf)(x) = g(f(g^{-1}x))) is an isomorphism.

**Remark 1.12.2** Tate’s theorem is also true for function fields over finite fields (Zarhin) and fields that are finitely generated over their prime field (Faltings), e.g. number fields. Not true over algebraically closed fields though.

1.12.2 Motivation

Let \(\pi_A\) and \(\pi_B\) be the (relative) Frobenii on \(V_l(A), V_l(B)\)

\[
\text{Hom}_k(A, B) \otimes \mathbb{Q}/l \to \text{Hom}_G(V_l A, V_l B)
\]

\(P_A, P_B\) characteristic polynomials of \(\pi_A, \pi_B\).

Toy Weil conjectures: \(P_A, P_B\) have \(\mathbb{Z}\)-coefficients, don’t depend on the choice of \(l\). Provided that induced action of Frobenii are semisimple, we can find a number \(r(P_A, P_B)\) then Tate implies

\[
\dim_{\mathbb{Q}} \text{Hom}_G(V_l(A), V_l(B)) = \text{rank} \text{Hom}_k(A, B)
\]

**Corollary 1.12.3** Let \(A, B\) be abelian varieties over \(F_q\) and \(P_A, P_B\) as above

1. \(\text{rank} \text{Hom}_k(A, B) = r(P_A, P_B)\)

2. **TFAE**
   
   (a) \(B\) is \(k\)-isogenous to an abelian subvariety of \(A\)
   
   (b) \(V_l B\) is \(G\)-isomorphic to a \(G\)-subrepresentation of \(V_l A\) for \(l \neq \text{char} k\)
   
   (c) \(P_B | P_A\)

we also have similar statements for equivalence, but get a nice statement about counting points over all extensions determining an abelian variety.

**Proof.**

\[
\alpha : V_l(B) \hookrightarrow V_l(A)
\]

the surjectivity in Tate’s theorem means we can choose \(u \in \text{Hom}_k(B, A) \otimes \mathbb{Q}/l\). \(V_l(u) = \alpha\). Choose \(u \in \text{Hom}_k(B, A) \otimes \mathbb{Q}\) arbitrarily close to \(\alpha\). Lower semicontinuity implies if \(V_l(u)\) is close enough to \(\alpha\), can ensure \(V_l(u)\) is injective (\(\ker(V_l(u)) = 0\)) take multiple to get \(u \in \text{Hom}_k(B, A)\). Since \(T_l(u)\) is injective \(u\) is an isogeny to an abelian subvariety.

1.12.3 Isogeny category

Recall: The isogeny category, **Theorem 1.7.1, Corollary 1.7.3.** So we have a category \(\mathcal{I}_{/k}\) of abelian varieties with

\[
\text{Hom}_{\mathcal{I}_{/k}}(A, B) = \text{Hom}_{AV}(A, B) \otimes \mathbb{Q}.
\]
Now if \( f : A \rightarrow B \) there exists \( g : B \rightarrow A \) an isogeny and \( n \in \mathbb{Z}_{\geq 1} \) s.t. \( g f = [n] \). So \( \frac{1}{n} g \) is an inverse for \( f \in I \mathfrak{k} \) so isogenies are isomorphisms in \( I \mathfrak{k} \).

\( I \mathfrak{k} \) is a semisimple abelian category. The simples are simple abelian varieties.

1. Decomposition up to isogeny into a product of simple abelian varieties is unique.

2. If \( A \) is simple \( \text{End} \ A \otimes \mathbb{Q} \) is a division algebra over \( \mathbb{Q} \). Reason: If \( A \) is simple in an abelian category, if \( \text{End} \ A \supseteq k \) a field implies it’s a division algebra.

### 1.12.4 Reductions

**Lemma 1.12.4**

1.

\[
\mathbb{Z}_l \otimes \text{Hom}_{AV}(A, B) \rightarrow \text{Hom}_{T_l}(T_l, T_l B)
\]

is an isomorphism if and only if

\[
\mathbb{Q}_l \otimes \text{Hom}_{AV}(A, B) \rightarrow \text{Hom}_{C}(V_l A, V_l B)
\]

is an iso

2. If for every \( C \),

\[
\mathbb{Q}_l \otimes \text{End}_{AV}(C) \rightarrow \text{End}_{C}(V_l C)
\]

is an isomorphism then the above is an isomorphism for every pair \( A, B \).

**Proof.**

1. The first map is always injective, the cokernel is torsion free, hence free. It’s an isomorphism if and only if \( \mathbb{Q}_l \otimes \text{coker} = 0 \) As \( \mathbb{Q}_l \) is flat over \( \mathbb{Z}_l \) the second map injective and its cokernel is \( \mathbb{Q}_l \otimes \) the cokernel of the first map.

2.

\[
C = A \times B
\]

then

\[
\text{End}^0(C) = \text{End}^0(A) \oplus \text{Hom}^0(A, B) \oplus \text{Hom}^0(B, A) \oplus \text{End}^0(B)
\]

and

\[
\text{End}_{C}(V_l C) = \text{End}_{C}(V_l A) \oplus \text{Hom}_{C}(V_l A, V_l B) \oplus \text{Hom}_{C}(V_l B, V_l A) \oplus \text{End}_{C}(V_l B)
\]

which the injection above preserves, in particular if the last map is an isomorphism, so are the rest.

\[
\square
\]

One more reduction!

\[
E_l = \text{End}_{k}(A) \otimes \mathbb{Q}_l \subseteq \text{End}_{\mathbb{Q}_l}(V_l A)
\]

\[
F_l = \mathbb{Q}_l [\mathcal{G}] \subseteq \text{End}_{\mathbb{Q}_l}(V_l A)
\]

automorphisms of \( V_l(A) \) coming from \( \mathcal{G} \).

**Note 1.12.5** \( E_l \) coming from \( k \)-rational endomorphisms commute with the
Galois action
\[ F_i \subseteq \text{End}_\mathbb{Q}(V_l(A))(E_i) \]
want equality.

**Lemma 1.12.6**

1. The last map of the reduction lemma is an isomorphism if and only if
\[ C(C(E_i)) = \text{End}_G(V_l(A)) \]

2. If \( F_i \) is semisimple the map is an isomorphism if and only if
\[ C(E_i) = F_i \]

**Proof.**

1. Double centralizer theorem, if \( E_l \) is semisimple then \( C(C(E_l)) \) is a finite dimensional division algebra over \( \mathbb{Q} \). A matrix algebra over a finite dimensional division algebra is semisimple.

2. If \( F_l \) is semisimple
\[ C(E_l) \subseteq F_l \Longleftrightarrow E_l = C(C(E_l)) \]

so
\[ E_l = C(F_l) = \text{End}_G(V_l(A)). \]

\[ \blacksquare \]

**1.12.5 Proof of Tate using finiteness**

We introduce a hypothesis: \( \text{Hyp}(k, A, l) \) there exist only finitely many (up to \( k \)-isomorphism) abelian varieties \( B \) s.t. there is a \( k \)-isogeny of \( l \)-power degree from \( B \to A \).

\[ D = C(E_l) \] want that \( C(D) = \text{End}_G(V_l(A)) \) know \( C(D) \subseteq E_l \subseteq \text{End}_G(V_l(A)) \) want \( C(D) \supseteq \text{End}_G(V_l(A)) \). Let \( \alpha \in \text{End}_G(V_l(A)) \) show that it commutes with everything in \( D \). Equivalently let \( W \) be the graph of \( \alpha \)
\[ W = \{(x, \alpha x) \in V_l(A) \times V_l(A) \} \subseteq V_l(A) \times V_l(A) \]

note \( g \in G \) then \( g \cup (x, \alpha x) = (gx, g\alpha x) = (gx, \alpha(gx)) \).
\[ \alpha \in C(D) \iff \forall x \in V_l(A), d \in D \]
\[ adx = dax \iff (d \oplus d)W \subseteq W \forall d \in D \]
\[ W \ni (dx, d\alpha x) = (dx, \alpha(d)) \]

**Lemma 1.12.7 Technical lemma.** If \( W \subseteq V_l(A) \) is \( G \)-stable subspace then there exists \( u \in E_l \) s.t. \( uV_l(A) \) is \( W \).

**Proof.** For \( n \in \mathbb{Z}_{\geq 0} \) let \( U_n = (W \cap V_l(A)) + l^nT_A \) which is a \( G \)-stable lattice in \( V_l(A) \),
\[ l^nT_A \subseteq U_n \subseteq T_lA \]

let \( \mathcal{K}_n \subseteq A[l^n](k^\chi) = T_lA/l^nT_A \) be the image of \( U_n \). \( \mathcal{K}_n \) is stable under \( G- \)
action on $A[l^n](k^\ell)$ which implies $\mathcal{K}_n = K_n(k^\ell)$. Let $\pi_n: A \rightarrow B_n = A/K_n$, $\iota_n: B_n \rightarrow A$ unique isogeny s.t.

$$\iota_n \circ \pi_n = [l^n]_A$$

then $T_lB \cong U_n$ as $\mathbb{Z}_l$-modules with $G$-action. As $T_l(\iota_n): U_n = T_lB \rightarrow T_lA$ is the inclusion map. Assuming Hyp$(k, A, l)$ we can find $n = n_1 < n_2 < \cdots$ s.t. we have

$$\alpha_i: B_n \rightarrow B_{n_i}$$

$$\begin{array}{c}
B_n \xrightarrow{\alpha_i} B_{n_i} \\
\uparrow \pi_n \downarrow \iota_n \\
A \xrightarrow{\iota_{n_i}} A
\end{array}$$

$u_i = \iota_{n_i} \circ \alpha_i \circ \pi_n$ is an endomorphism of $A$ on Tate modules $T_l(u_i)$ is induced map

$$T_lA \rightarrow [l^n]_A U_n \xrightarrow{T_l\iota_{n_i}} U_{n_i} \rightarrow T_lA$$

because $\mathbb{Z}_l \otimes \text{End } A$ is a free $\mathbb{Z}_l$-module of finite rank compact in $l$-adic topology subsequence of $u_i \rightarrow u$ in $\mathbb{Z}_l \otimes \text{End } A$

$$U_{n_1} \supseteq U_{n_2} \supseteq \cdots$$

the endomorphism of $T_lu$ maps $T_lA$ to $\bigcap_{i=1}^{\infty} U_n = W \cap T_lA$ passing to $\mathbb{Q}_l$-coefficients, note $\mathbb{Q}_l(W \cap T_lA) = \mathbb{Q}_l([l^n](W \cap T_lA)) = W$ so $\text{im}(V_l(u)) = W$. 

Why does the hypothesis hold.

**Fact 1.12.8** There exists a moduli space of $d$-polarised abelian varieties of dim $= g$ $A_{g,d}$ which is a stack of finite type $/k$.

$$A_{g,d}(k) = \{(A, \lambda): A, \lambda: A \rightarrow A^{\vee}, \deg \lambda\}$$

Zahrin’s trick: $A$ abelian variety $(A \times A^{\vee})^4$ is principally polarized. Finiteness of direct factors $B \subseteq A \cong B \times C$.

**Corollary 1.12.9** If $k = F_q$ exists only finitely many isogeny classes of abelian varieties of dim $g$.

**Proof.** $A$ is a direct factor $(A \times A^{\vee})^4 \in A_{g,1}$.

**Proof.** of Tate.

Apply technical lemma to $V_l(A \times A)$ and $W$ so

$$(d \oplus d)W = (d \oplus d)uV_l(A \times A) = u(d \oplus d)V_l(A \times A) \subseteq uV_l(A \times A) = W$$

$$\implies C(D) \supseteq \text{End}_C(V_l(A)).$$

1.13 The Honda Tate Theorem (Angus)

$q = p^n$, $A$ a simple abelian variety over $F_q$, $\pi_A$ the frobenius on $A$, $\text{End}^0(A) = Q \otimes \text{End}(A)$, $f_A$ is the charpoly of $A$ (i.e. of $\pi_A$).

**Fact 1.13.1**

- $\text{End}^0(A)$ is a division ring.
• \( \mathbb{Q}[\pi] \) is a field.

• \( \mathbb{Z}(\text{End}^0(A)) = \mathbb{Q}[\pi_A] \)

**Lemma 1.13.2 The Weil Conjectures.** The roots of \( f_A \) all have absolute value \( \sqrt{q} \).
Alternatively, under all embeddings \( \iota : \mathbb{Q}[\pi] \hookrightarrow \mathbb{C}, |\iota(\pi)| = \sqrt{q} \).

**Definition 1.13.3** \( q \)-Weil numbers. A \( q \)-Weil number is an algebraic integer \( \pi \) s.t.
\( \forall \iota : \mathbb{Q}[\pi] \hookrightarrow \mathbb{C}, |\iota(\pi)| = \sqrt{q} \)
we say that two \( q \)-Weil numbers are conjugate if they have the same minimal polynomial over \( \mathbb{Q} \), and write \( \pi \sim \pi' \).

From the facts so far we have a map
\( \{\text{simple AVs}/\mathbb{F}_q\} \rightarrow \{\text{\( q \)-Weil numbers}\} \)
\( A \mapsto \pi_A \)

**Theorem 1.13.4** We have a bijection
\( \{\text{isogeny classes of simple AVs}/\mathbb{F}_q\} \overset{\sim}{\longrightarrow} \{\text{conjugacy classes of \( q \)-Weil numbers}\} \)
\( A \mapsto \pi_A. \)

We need to show this is well-defined, injectivity and surjectivity.

**1.13.1 Honda-Tate map**
Recall:

**Corollary 1.13.5** Let \( A, B \) be abelian varieties over \( \mathbb{F}_q \) with rational Tate modules \( V_lA, V_lB \) then
\( A \sim_{\text{isog}} B \iff V_lA \cong V_lB \forall l \neq p. \)

**Corollary 1.13.6**
\( A \sim_{\text{isog}} B \iff f_A = f_B \)

**Proof.** By above \( V_lA \cong V_lB \) for all \( l \neq p \) but \( f_A \) (resp. \( f_B \)) is the charpoly of \( \pi_a \) (\( \pi_B \)) on \( V_lA \) (\( V_lB \)).
The Galois modules \( V_lA \) and \( V_lB \) are semisimple. The Brauer-Nesbitt theorem says \( f_A = f_B \implies V_lA \cong V_lB \) for \( l \neq p. \)
Recalling that \( f_A \) is a power of the minimal polynomial of \( \pi_A, \)
\( A \sim_{\text{isog}} B \implies f_A = f_B \implies \pi_A \sim \pi_B. \)
So the Honda-Tate map is well defined.
This doesn’t quite give injectivity because a priori \( f_A \) and \( f_B \) could be powers of the minpolys of \( \pi_A, \pi_B. \)

**1.13.2 Injectivity and Brauer groups**
From last time:

**Proposition 1.13.7** There exists a certain quantity \( r(f_A, f_B) \) such that
\( r(f_A, f_B) = \text{rank Hom}(A, B). \)
Corollary 1.13.8 Let \( d = [\text{End}^0(A) : \mathbb{Q}(\pi_A)]^{1/2} \), let \( h_A = \text{minpoly}_\mathbb{Q}(\pi_A) \) then \( f_A = h_A^d \).

Proof. Study the formula for \( r(f_A, f_A) \) Edixhoven-van der Geer-Moonen 16.22. ■

So the next step is to try and recover \( \text{End}^0(A) \) from \( \pi \).

Definition 1.13.9 Central simple algebras. A central simple algebra \( B/k \) is a \( k \)-algebra with no two-sided ideals and \( Z(B) = k \). ◊

Theorem 1.13.10 Artin-Wedderburn. Any such algebra is isomorphic to \( M_n(D) \) for \( D \) a division ring over \( k \).

Definition 1.13.11 Brauer groups. The Brauer group \( \text{Br}(k) \) is the set of central simple algebras under \( \otimes \) modulo the algebras \( M_n(k) \). ◊

Fact 1.13.12
- If \( k = \overline{k} \), \( \text{Br}(k) = 0 \).
- \( k \) complete nonarchimedean \( \text{Br}(k) = \mathbb{Q}/\mathbb{Z} \)
- \( \text{Br}(R) = \mathbb{Z}/2\mathbb{Z} \)

Given a place \( v \) of \( k \) we get a map

\[
\text{Br}(k) \to \text{Br}(k_v)
\]

\[D \mapsto D \otimes k_v\]

in fact we get an injection

\[
\text{Br}(k) \hookrightarrow \prod_v \text{Br}(k_v) = \prod_{v \text{ nonarch}} \mathbb{Q}/\mathbb{Z} \times \prod_{v \text{ real}} \mathbb{Z}/2\mathbb{Z}
\]

\[D \mapsto (\text{inv}_v(D))_v\]

these \( \text{inv}_v(D) \) are called the local invariants.

Proposition 1.13.13 Let \( A/F_q \) be an elementary abelian variety. Let \( K = \mathbb{Q}(\pi_A) \) then

\[
\text{inv}_v(\text{End}^0(A)) = \begin{cases} \frac{v(\pi_A)}{v(q)}[k_v : \mathbb{Q}_p], & v|p \\ \frac{1}{2}, & v \text{ real} \\ 0, & \text{else} \end{cases}
\]

Proposition 1.13.14 Let \( d = [\text{End}^0(A) : \mathbb{Q}(\pi_A)]^{1/2} \) then \( d \) is the least common denominator of all the \( \text{inv}_v(\text{End}^0(A)) \).

Corollary 1.13.15

\[
\pi_A \sim \pi_B \iff f_A = f_B.
\]

Proof. \iff done.

\Rightarrow Let \( D_{\pi_A}, D_{\pi_B} \) be the division rings with invariants specified as in Proposition 1.13.13. \( \pi_A \sim \pi_B \Rightarrow D_{\pi_A} \simeq D_{\pi_B} \Rightarrow f_A = \text{minpoly}(\pi_A)^d = f_B. \) ■

1.13.3 Surjectivity and CM theory

We need to show that for \( \pi \) a \( q \)-Weil number there exists an abelian variety \( A/F_q \) such that \( \pi_A \sim \pi \).
Definition 1.13.16 Such a \( q \)-Weil number \( \pi \) is called effective. ♦

Proposition 1.13.17 A \( q \)-Weil number \( \pi \) is effective if and only if \( \pi^N \) is effective for some \( N \in \mathbb{Z}_{\geq 1} \).

Proof. \( \Rightarrow \) clear.

\( \Leftarrow \) By assumption we have \( A'/k \) a simple abelian variety s.t. \( \pi_{A'} \sim \pi^N \) for \( k \) a degree \( N \) extension of \( \mathbb{F}_q \). Let

\[ A = \text{Res}_{k/F_q}(A') \]

on the rational Tate modules we have

\[ V_iA = \text{Ind}^G_{G_{k_i}}(V_iA') \]

where

\[ G_k = \text{Gal}(\overline{F}_q/k) \]

\[ G_{F_q} = \text{Gal}(\overline{F}_q/F_q) \]

since \( G_k, G_{F_q} \) are abelian, by studying the induced action, one can see

\[ \text{Ind}^G_{G_{k_i}}(\pi_{A'}) = \pi^N_A \]

in particular \( f_A(T) = f_{A'}(T^N) \). Choosing a simple factor \( A_i \) one gets \( \pi_{A_i} \sim \pi \).

So it is sufficient to show \( \pi^N \) is effective.

Strategy for proving surjectivity

1. Construct a division algebra \( D_\pi \).
2. Choose a CM field \( L \) splitting \( D_\pi \).
3. Find an abelian variety \( A/C \) of type \( (L, \Phi) \).
4. In fact \( A \) is defined over a number field \( K \) and has good reduction at \( v|p \).
5. Apply the Shimura-Taniyama formula to relate \( \pi_A \) to \( \Phi \).
6. Choose \( \Phi \) wisely (in retrospect in 3) to relate \( \pi \) to \( \pi_A \).
7. Show \( \pi^N_A = \pi^N \).

\( D_\pi \) is given by the invariants described by \( \pi \) (and \( K = \mathbb{Q}(\pi) \)).

Proposition 1.13.18 There exists a CM field \( L/\mathbb{Q}(\pi) \) such that \( L \) splits \( D_\pi \) and further

\[ [L : \mathbb{Q}(\pi)] = [D_\pi : \mathbb{Q}(\pi)]^{1/2} \]

Proof. Two cases:

1. \( \mathbb{Q}(\pi) \) is totally real, in which case \( \mathbb{Q}(\pi) = \mathbb{Q} \) or \( \mathbb{Q}(\sqrt{p}) \).
2. \( \mathbb{Q}(\pi) \) is a CM field with totally real subfield \( \mathbb{Q}(\pi + q/\pi) \).

In the case

1. Choose \( L = \mathbb{Q}(\pi)(\sqrt{-p}) \).
2. Let \( d = [D_\pi : \mathbb{Q}(\pi)]^{1/2} \). This \( L \) splits \( D_\pi \).

■
Definition 1.13.19 CM types. For a CM field \( L \) all the embeddings
\( \iota: L \hookrightarrow \mathbb{C} \)
come in complex conjugate pairs, choosing an embedding for each pair defines a subset \( \Phi \subseteq \text{Hom}(L, \mathbb{C}) \) such that
\[
\Phi \cup \overline{\Phi} = \text{Hom}(L, \mathbb{C}) \\
\Phi \cap \overline{\Phi} = \emptyset
\]
such a choice of \( \Phi \) is called a CM type. ♦

Let \( A/\mathbb{C} \) be an abelian variety with CM by \( L \) i.e.
\( L \hookrightarrow \text{End}^0(A) \)
then
\( \mathbb{C} \otimes L = \prod_i \mathbb{C} \)
acts on the tangent space at the origin \( \text{Lie}(A) \).

Proposition 1.13.20 The action of \( \mathbb{C} \otimes L \) factors through the quotient \( \prod_{\iota \in \Phi} \mathbb{C} \) for some CM type \( \Phi \). We then say \( A/\mathbb{C} \) is of type \( (L, \Phi) \).

Theorem 1.13.21 For any CM type \( (L, \Phi) \) there exists an abelian variety \( A/\mathbb{C} \) of type \( (L, \Phi) \).
Proof. Found in Shimura-Taniyama. ■

The fact that \( A \) is in fact defined over a number field \( K \) is also in Shimura-Taniyama.

Theorem 1.13.22 Let \( A/K \) be an abelian variety which admits CM. Then \( A/K \) admits potentially good reduction at all places \( v \) of \( K \).
Proof. Highly nontrivial, Neron models, Chevalley decomposition, Neron-Ogg-Shafarevich criterion, result of Grothendieck on potentially stable reduction. ■

After passing to a finite extension we will assume \( A/K \) has good reduction at places \( v \mid p \). So we have a reduction \( A_{F_q}/F_q' \). For a place \( w \mid p \) of \( L \) let
\[
\Sigma_w = \text{Hom}(L_w, \mathbb{C}_p) \\
\Phi_w = \Phi \cap \Sigma_w.
\]

Theorem 1.13.23 Shimura-Taniyama formula. For all places \( w \mid p \) of \( L \),
\[
\frac{w(\pi_{A_{F_q}'})}{w(q^*)} = \frac{\#\Phi_w}{\#\Sigma_w}
\]
Proof. Tate has a proof using CM theory of \( p \)-divisible groups. ■

Recall we fixed \( \pi \) and from this we deterministically formed \( \mathbb{Q}(\pi), D_\pi, L \) however we have no restriction on our choice of \( \Phi \).

Lemma 1.13.24 We can choose \( \Phi \) such that for all places \( w \mid p \) of \( L \),
\[
\frac{w(\pi)}{w(q)} = \frac{\#\Phi_w}{\#\Sigma_w}
\]
Proof. Let \( v = w|_{\mathbb{Q}(\pi)} \) be the place of \( \mathbb{Q}(\pi) \) below \( w \). Let
\[
n_w = \frac{w(\pi)}{w(q)} \frac{\#\Sigma_w}{\#\Phi_w} = \frac{w(\pi)}{w(q)} [L_w : \mathbb{Q}_p]
\]
\[
\frac{w(\pi)}{w(q)} \left[L_w : \mathbb{Q}(\pi)^2\right] [\mathbb{Q}(\pi)_p : \mathbb{Q}_p]
\]
by recalling the formula for the local invariants of \(D_{\pi}\) we get

\[
n_w = \text{inv}_w(D_{\pi} \otimes_{\mathbb{Q}(\pi)} L).
\]

But \(L\) splits \(D_{\pi}\) so \(n_w \in \mathbb{Z}\), further

\[
n_w + n_w' = \left(\frac{w(\pi)}{w(q)} + \frac{\overline{w}(\pi)}{w(q)}\right) \# \Sigma_w
\]

\[
= \left(\frac{w(\pi \overline{\pi})}{w(q)}\right) \# \Sigma_w = \# \Sigma_w
\]

check the CM type \(\Phi = \bigcup_w \Phi_w\) where for each \(w \# \Phi_w = n_w\). Then the formula follows.

Combining the previous result with the Shimura-Taniyama formula we get that for all places \(w|p\)

\[
\frac{w(\pi_{A_{F'}})}{w(q')} = \frac{w(\pi)}{w(q)}.
\]

Taking the correct power,

\[
w\left(\frac{\pi_{A_{F'}}^m}{\pi_{A_{F'}}^{m'}}\right) = 0 \forall w|p
\]

\[
\pi, \pi_{A_{F'}} | q^{m'}
\]

\[
\implies w(\cdots) = 0 \forall w \nmid p
\]

since \(|\pi_{A_{F'}}^m|_w = |\pi_{A_{F'}}^m|_w = (q^m)^{1/2} \forall\) infinite places

\[
\pi_{A_{F'}} / \pi_A
\]

is a root of unity \(\pi_{A_{F'}}^N = \pi_{A_{F'}}^N\).
Chapter 2

Dessins d’Enfants

These are notes for BUNTES Spring 2018, the topic is Dessins d’Enfants, they were last updated September 10, 2019. For more details see the webpage. These notes are by Alex, feel free to email me at alex.j.best@gmail.com to report typos/suggest improvements, I’ll be forever grateful.

2.1 Overview (Angus)

2.1.1 Belyi morphisms

Let \( X \) be an algebraic curve over \( \mathbb{C} \) (i.e. a compact Riemann surface) when is \( X \) defined over \( \mathbb{Q} \)?

**Theorem 2.1.1 Belyi.** An algebraic curve \( X/\mathbb{C} \) is defined over \( \mathbb{Q} \) if and only if there exists a morphism \( \beta: X \to \mathbb{P}^1 \mathbb{C} \) ramified only over \( \{0, 1, \infty\} \).

**Definition 2.1.2 Ramified.** (AG) A morphism \( f: X \to Y \) is **ramified** at \( x \in X \) if on local rings the induced map \( f^\#: \mathcal{O}_{Y,f(x)} \to \mathcal{O}_{X,x} \) descended to

\[ \mathcal{O}_{Y,f(x)}/m \to \mathcal{O}_{X,x}/f^\#(m) \]

is not a finite separable field extension.

(RS) A morphism \( f: X \to Y \) is ramified at \( x \in X \) if there are charts around \( x \) and \( f(x) \) such that \( f(x) = x^n \). This \( n \) is the **ramification index**.

**Definition 2.1.3 Belyi morphisms.** A **Belyi morphism** is one ramified only over \( \{0, 1, \infty\} \)

A **clean Belyi morphism** or **pure Belyi morphism** is a Belyi morphism where the ramification indices over 1 are all exactly 2.

**Lemma 2.1.4** A curve \( X \) admits a Belyi morphism iff it admits a clean Belyi morphism.

**Proof.** If \( \alpha: X \to \mathbb{P}^1 \mathbb{C} \) is Belyi, then \( \beta = 4\alpha(1 - \alpha) \) is a clean Belyi morphism.

2.1.2 Dessin d’Enfants

**Definition 2.1.5** A **dessin d’Enfant** (or Grothendieck Dessin or just Dessin) is a triple \((X_0, X_1, X_2)\) where \( X_2 \) is a compact Riemann surface, \( X_1 \) is a graph, \( X_0 \subset X_1 \) is a finite set of points, where \( X_2 \setminus X_1 \) is a collection of open cells, \( X_1 \setminus X_0 \) is a disjoint union of line segments

47
Lemma 2.1.6 The data of a dessin is equivalent to a graph with an ordering on the edges coming out of each vertex.

Definition 2.1.7 Clean dessins. A clean dessin is a dessin with a colouring (white and black) on the vertices such that adjacent vertices do not share a colour.

2.1.3 The Grothendieck correspondence

Given a Belyi morphism $\beta : X \to \mathbb{P}^1 \mathbb{C}$ the graph $\beta^{-1}([0,1])$ defines a dessin.

Theorem 2.1.8 The map

$$\{(\text{Clean}) \ Belyi \ morphisms\} \to \{(\text{clean}) \ dessins\}$$

$\beta \mapsto \beta^{-1}([0,1])$

is a bijection up to isomorphisms.

Example 2.1.9

$$\mathbb{P}^1 \mathbb{C} \to \mathbb{P}^1 \mathbb{C}$$

$x \mapsto x^3$

$$\mathbb{P}^1 \mathbb{C} \to \mathbb{P}^1 \mathbb{C}$$

$x \mapsto x^3 + 1$

2.1.4 Covering spaces and Galois groups

A Belyi morphism defines a covering map.

$$\tilde{\beta} : \tilde{X} \to \mathbb{P}^1 \mathbb{C} \setminus \{0, 1, \infty\}$$

the coverings are controlled by the profinite completion of

$$\pi_1(\mathbb{P}^1 \mathbb{C} \setminus \{0, 1, \infty\}) = \mathbb{Z} \ast \mathbb{Z} = F_2.$$

Theorem 2.1.10 There is a faithful action

$$\text{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}) \cup \hat{\pi}_1(\mathbb{P}^1 \mathbb{C} \setminus \{0, 1, \infty\})$$

Proof. By Belyi’s theorem every elliptic curve $E/\overline{\mathbb{Q}}$ admits a Belyi morphism.

For each $j \in \overline{\mathbb{Q}}$ there exists an elliptic curve $E_j/\overline{\mathbb{Q}}$ with $j$-invariant $j$.

Given $\sigma \in \text{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$,

$$\sigma(E_j) = E(\sigma(j))$$

assume $\sigma \mapsto 1$,

$$E_j \cong E_{\sigma(j)} \ \forall j$$

$$j = \sigma(j) \ \forall j$$

a contradiction.

Corollary 2.1.11 We have a faithful action of $\text{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$ on dessins.

Theorem 2.1.12 We have a faithful action of $\text{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$ on the set of dessins of any fixed genus.
2.1.5 Exercises

Exercise 2.1.13 Compute the Dessins for the following Belyi morphisms

1. \( \mathbb{P}^1 \mathbb{C} \to \mathbb{P}^1 \mathbb{C}, \ x \mapsto x^4 \)

2. \( \mathbb{P}^1 \mathbb{C} \to \mathbb{P}^1 \mathbb{C}, \ x \mapsto x^2(3 - 2x) \)

3. \( \mathbb{P}^1 \mathbb{C} \to \mathbb{P}^1 \mathbb{C}, \ x \mapsto \frac{1}{x(2 - x)} \)

Exercise 2.1.14 Give an alternate proof of the fact that \( X \) admits a Belyi morphism if and only if it admits a clean Belyi morphism using dessins and the Grothendieck correspondence.

Exercise 2.1.15 Prove that a Belyi morphism corresponding to a tree, that sends \( \infty \) to \( \infty \) is a polynomial.

2.2 Riemann Surfaces I (Ricky)

2.2.1 Definitions

Definition 2.2.1 A topological surface is a Hausdorff space \( X \) which has a collection of charts

\[ \{ \phi_i : U_i \sim \phi_i(U_i) \subseteq \mathbb{C}, \text{open} \}_{i \in I} \]

such that

\[ X = \bigcup_{i \in I} U_i. \]

We call \( X \) a Riemann surface if the transition functions \( \phi_i \circ \phi_j^{-1} \) are holomorphic.

2.2.2 Examples

Example 2.2.2 Open subsets of \( \mathbb{C} \), e.g.

\[ \mathbb{C} \]

\[ \mathbb{D} = \{ z \in \mathbb{C} : |z| < 1 \} \]

\[ \mathbb{H} = \{ z \in \mathbb{C} : \text{im} z > 0 \}. \]

Example 2.2.3 \( \hat{\mathbb{C}} = \) Riemann sphere = \( \mathbb{C} \cup \{ \infty \} \). A basis of neighborhoods of \( \infty \) is given by

\[ \{ z \in \mathbb{C} : |z| > R \} \cup \{ \infty \}. \]

Example 2.2.4

\[ \mathbb{P}^1(\mathbb{C}) = \{ [z_0 : z_1] : (z_0, z_1) \neq (0, 0) \} \]

\[ U_0 = \{ [z_0, z_1] : z_0 \neq 0 \} \to \mathbb{C} \]
\[
[z_0 : z_1] \mapsto \frac{z_1}{z_0}
\]
\[U_1 = \{ [z_0, z_1] : z_1 \neq 0 \} \to \mathbb{C}
\]
\[[z_0 : z_1] \mapsto \frac{z_0}{z_1}.
\]

\[\square\]

Example 2.2.5 Let \( \Lambda = \mathbb{Z} \oplus \mathbb{Z} i \subseteq \mathbb{C} \) then \( X = \mathbb{C}/\Lambda \) is a Riemann surface. \( \square \)

2.2.3 Morphisms

Definition 2.2.6 (Holo/Mero)-morphisms of Riemann surfaces. A morphism of Riemann surfaces is a continuous map
\[f : S \to S',\]
such that for all charts \( \phi, \psi \) on \( S, S' \) respectively we have \( \psi \circ f \circ \phi^{-1} \) is holomorphic.

We call a morphism \( f : S \to \mathbb{C} \) a holomorphic function on \( S \).

We say \( f : S \to \mathbb{C} \) is a meromorphic function is \( f \circ \phi^{-1} \) is meromorphic. \( \diamond \)

Exercise 2.2.7 The set of meromorphic functions on a Riemann surface form a field.

We denote the field of meromorphic functions by \( M(S) \).

Proposition 2.2.8 1.26.
\[M(\hat{\mathbb{C}}) = \mathbb{C}(z).
\]

Proof. Let \( f : \hat{\mathbb{C}} \to \mathbb{C} \) be meromorphic. Then the number of poles of \( f \) is finite say at \( a_1, \ldots, a_n \). So, locally at \( a_i \) we can write
\[f(z) = \sum_{j=1}^{l_i} \frac{\lambda_{j,i}}{(z-a_i)^j} + h_i(z)
\]
with \( h_i \) holomorphic. Then
\[f(z) - \sum_{i=1}^{n} \sum_{j=1}^{l_i} \frac{\lambda_{j,i}}{(z-a_i)^j}
\]
is holomorphic everywhere. By Liouville’s theorem this is constant. \( \square \)

We say \( S, S' \) are isomorphic if \( \exists f : S \to S', g : S' \to S \) morphisms such that \( f \circ g = \text{id}_{S'} \), \( g \circ f = \text{id}_S \).

Exercise 2.2.9 Show that \( \hat{\mathbb{C}} \cong \mathbb{P}^1(\mathbb{C}) \).

Remark 2.2.10 \( \mathbb{C} \neq \mathbb{D} \) by Liouville.

If \( S, S' \) are connected compact Riemann surfaces, then any nonconstant morphism \( f : S \to S' \) is surjective. (Nonconstant holomorphic maps are open)
2.2.4 Ramification

Definition 2.2.11 Orders of vanishing. The order of vanishing at $P \in S$ of a holomorphic function on $S$ is defined as follows: For $\phi$ a chart centered at $P$ write

$$f \circ \phi^{-1}(z) = a_n z^n + a_{n+1} z^{n+1} + \cdots, \quad a_n \neq 0$$

then $\text{ord}_P(f) = n$.

More generally, for $f : S \to S'$ we can define $m_P(f)$ (multiplicity of $f$ at $P$) by using a chart $\psi$ on $S'$ and setting

$$m_P(f) = \text{ord}_P(\psi \circ f).$$

If $m_P(f) \geq 2$ then we call $P$ a branch point of $f$ and call $f$ ramified at $P$. ♦

Example 2.2.12 $f : \mathbb{C} \to \mathbb{C}$, $f(z) = z^2$.

The chart $\phi_a(z) = z - a$ is centered at $a \in \mathbb{C}$. Then to compute $m_a(f)$ we compute

$$f \circ \phi_a^{-1}(z) = a^2 + 2a z + z^2$$

hence

$$\text{ord}_a(f) = \begin{cases} 0, & \text{if } a \neq 0 \\ 2, & \text{if } a = 0 \end{cases}.$$  

2.2.5 Genus

Theorem 2.2.13 Rado. Any orientable compact surface can be triangulated.

Fact 2.2.14 Riemann surfaces are orientable.

Given such an oriented polygon coming from a Riemann surface, we can associate a word $w$ to it from travelling around the perimeter.

Example 2.2.15 For the sphere $w = a^{-1} b^{-1} c^{-1}$.

Fact 2.2.16 Every such word can be normalised without changing the corresponding Riemann surface.

$$w = \begin{cases} w_0 = aa^{-1} \\ w_g = a_1 b_1 a_1^{-1} b_1^{-1} \cdots a_g b_g a_g^{-1} b_g^{-1} \end{cases}$$

The (uniquely determined) $g$ is the genus of the surface.

Example 2.2.17 $w_1 = a_1 b_1 a_1^{-1} b_1^{-1}$.

$w_2 = a_1 b_1 a_1^{-1} b_1 a_2 b_2 a_2^{-1} b_2^{-1}$. ♦

Theorem 2.2.18

$$\chi(S) = v - e + f = 2 - 2g(S).$$

2.3 Riemann Hurwitz Formula (Sachi)

Exercise 2.3.1 Unimportant. The genus is invariant under changing triangulation.
In particular there are at least two distinct ways of thinking about genus for Riemann surfaces $R$:

1. 

$$\chi(R) = V - E + F = 2 - 2g$$

2. The dimension of the space of holomorphic differentials on $R$.

Goal: given $R$ calculate genus

$$y^2 = (x + 1)(x - 1)(x + 2)(x - 2)$$

so in an ad hoc way

$$y = \sqrt{(x + 1)(x - 1)(x + 2)(x - 2)}$$

when $x$ is not a root of the above we have two distinct values for $y$, we can imagine two copies of $\mathbb{C}$ sitting above each other and then square root will land in both copies. We have to make branch cuts between the roots and glue along these to account for the fact that going around a small loop surrounding a root will change the sign of our square root. We end up with something looking like a torus here.

Here we examined the value where there were not enough preimages when we plugged in a value for $x$. The idea is to project to $x$, and understand the number of preimages.

$$P(x, y) = y^n + p_{n-1}(x)y^{n-1} + \cdots + p_0(x)$$

an irreducible polynomial.

$$R = \{(x, y) : P(x, y) = 0\}.$$ 

If we fix $x_0 \in \mathbb{P}^1 \mathbb{C}$ we can analyse how many $y$ values lie over this $x$. If we have fixed our coefficients we expect $n$ solutions in $y$ over $\mathbb{C}$, i.e. points $(x_0, y) \in R$.

For some values of $x_0$ this will not be true, there will be fewer $y$-values, this occurs when we have a multiple root. This happens precisely when the discriminant of this polynomial vanishes, the discriminant is a polynomial and so has finitely many roots.

**Definition 2.3.2 Branch points.** Let $\pi : R \to \mathbb{P}^1 \mathbb{C}$. We say $x_0$ is a branch point if there are fewer than $n$ distinct $y$-values above $x$. Then define the total branching index

$$b = \sum_{x \in \mathbb{P}^1 \mathbb{C}} (\deg(\pi) - \#\pi^{-1}(x)).$$

**Claim 2.3.3**

$$\chi(R) = \deg \pi \cdot \chi(\mathbb{P}^1 \mathbb{C}) - b.$$ 

**Lemma 2.3.4** Locally given some choice of coordinates a non-constant morphism of Riemann surfaces

$$f : R \to S$$

is given by $w \mapsto w^n$. More precisely given $r \in R$, $f(r) = s$ and $V_s \ni s$ a small neighbourhood choose an identification of

$$V_s \to D$$
which sends $s \mapsto 0$ and we can find an analytic identification

$$r \in R, \phi \rightarrow D$$

such that

$$f(U_r) \subseteq V_s.$$
\[ df_d + (d - 1)f_{d-1} + \cdots + f_1 = 0 \]

\[
\begin{cases}
  f_d + f_{d-1} + \cdots + f_0 = 0 \\
  f_{d-1} + 2f_{d-2} + \cdots + (d-1)f_1 = 0
\end{cases}
\]

Now these have \( d(d - 1) \) common solutions. \( C^* \) has degree \( d(d - 1) \) so \( b = d(d - 1) \). Riemann-Hurwitz implies
\[
\chi(R) = 2 \deg \pi - d(d - 1)
\]
\[
\chi(R) = 2d - d(d - 1)
\]
so
\[
g = \frac{(d - 1)(d - 2)}{2}
\]

\[\square\]

**A 3-fold equivalence of categories.** Amazing synthesis.

1. **Analysis:** Compact connected riemann surfaces.
2. **Algebra:** Field extensions \( K/\mathbb{C} \) where \( K \) is finitely generated of transcendence degree 1 over \( \mathbb{C} \).
3. **Geometry:** Complete nonsingular irreducible algebraic curves in \( \mathbb{P}^n \).

3) curve \( \rightarrow \) 2) field extension. Over \( \mathbb{C} \) all rational functions \( \frac{P(x)}{Q(x)} \) \( \deg P = \deg Q, P, Q: \mathbb{C} \to \mathbb{C} \cup \{\infty\} \).

3) \( \rightarrow \) 1) take complex structure induced by \( \mathbb{P}^n \).

1) \( \rightarrow \) 2) associated field of meromorphic functions on \( X \).

1) \( \rightarrow \) 3) Any curve which is holomorphic has an embedding into \( \mathbb{P}^n \) (Riemann-Roch).

2) \( \rightarrow \) 1) \( K/\mathbb{C} \) consider valuation rings \( R \) such that \( K \supseteq R \supseteq \mathbb{C} \).

**Example 2.3.6** \( g = 0 \), \( \mathbb{P}^1 \subseteq \mathbb{C}(t), \mathbb{C} \cup \{\infty\} \).

**Example 2.3.7** \( g = 1 \), elliptic curves, \( f(x, y, z) \) smooth plane cubic, \( f = 0 \), \( \mathbb{C}(\sqrt{f(x)}, x) \).

\[ \mathbb{C}/\Lambda \to \mathbb{P}^2 \]

\[
z \mapsto (z, \wp(z), \wp'(z))
\]

\[z \notin \Lambda\]

backwards
\[
(x, y) \mapsto \int_{(x_0, y_0)}^{(x, y)} \frac{dx}{y}
\]

\[\square\]

**Riemann-Hurwitz (generally).** There’s nothing that doesn’t generalise about the previous proof.

**Claim 2.3.8** For \( \pi: R \to S \) a non-constant morphism of compact Riemann surfaces
\[
\chi(R) = \deg \pi \cdot \chi(S) - \sum_{x \in S} (\deg(\pi) - \#\pi^{-1}(x)).
\]
Corollary 2.3.9 There are no non-constant morphisms from a sphere to a surface of genus $> 0$.

Proof.

\[ f : \mathbb{P}^1 \mathbb{C} \to S \]
\[ \chi(\mathbb{P}^1 \mathbb{C}) = \deg f \chi(S) - b \]
\[ 2 = (+) \cdot (-) - b. \]

Exercise 2.3.10

\[ x^n + y^n + z^n = 0 \]
is not solvable in non-constant polynomials for $n > 2$.

Exercise 2.3.11

\[ E = \mathbb{C}/\mathbb{Z} + \mathbb{Z}i \]
multiplication by $i$ rotates $x \mapsto xi$ let $x \sim xi$. If we mod out by $\sim$ to get $E/\sim$ this is still a Riemann surface and the quotient map

\[ f : E \to E/\sim \]
is nice, compute the branch points of order 4 and order 2.

Exercise 2.3.12

$X$ compact Riemann surface of $g \geq 2$ then there are at most $84(g - 1)$ automorphisms of $X$.

Exercise 2.3.13 Klein quartic

\[ x^3y + y^3z + z^3x = 0 \]
has 168 automorphisms and is genus 3.

2.4 Riemann Surfaces and Discrete Groups (Rod)

Welcome to BUGLES (Boston university geometry learning expository seminar), the reason it is called bugles is because bugles are hyperbolic, and today we will see a lot of hyperbolic objects.

Plan

1. Uniformization
2. Fuchsian groups
3. Automorphisms of Riemann surfaces

Proposition 2.4.1

\[ \text{Aut}(\hat{\mathbb{C}}) = \{ z \mapsto \frac{az + b}{cz + d} \} \]
\[ \text{Aut}(\mathbb{C}) = \{ z \mapsto za + b \} \]
\[ \text{Aut}(\mathbb{H}) = \{ z \mapsto \frac{az + b}{cz + d}, a, b, c, d \in \mathbb{R} \} = \text{PSL}_2(\mathbb{R}) \]

Theorem 2.4.2 $\Sigma$ has a universal cover $\tilde{\Sigma}$ with $\pi_1(\Sigma) = 1$. $\tilde{\Sigma} \to \Sigma$ holomorphic. $\Sigma = \tilde{\Sigma}/G$ for $G = \pi_1(\Sigma)$. $G$ acts freely and properly discontinuously.
2.4.1 Uniformization

**Theorem 2.4.3** The only simply connected Riemann surfaces are \( \hat{\mathbb{C}}, \mathbb{C}, \mathbb{H} \).

**Theorem 2.4.4** \( \Sigma \) is a Riemann surface then

\[
g = 0 : \Sigma \cong \hat{\mathbb{C}} \\
g = 1 : \Sigma \cong \mathbb{C}/\Lambda \\
g \geq 2 : \Sigma \cong \mathbb{H}/K.
\]

**Proof.** \( g = 0 \) Uniformization.

\( g \geq 1 \) \( \hat{\mathbb{C}} \) can't be a cover by Riemann-Hurwitz. \( g = 1 \) \( \pi_1(\Sigma) = \mathbb{Z} \oplus \mathbb{Z} \) abelian.

Claim: no subgroup of \( \text{Aut}(\mathbb{H}) \) is isomorphic to \( \mathbb{Z} \oplus \mathbb{Z} \) acting freely and properly discontinuously. So \( \Sigma = \hat{\mathbb{C}} \) \( z \mapsto az + b \) free id \( a = 1 \) so \( z \mapsto z + \lambda_1 \) \( z \mapsto z + \lambda_2 \).

\( g = 2 \) \( \pi_1(\Sigma) \) is not abelian but \( z \mapsto z + \lambda_1 \) is abelian!

\( \Sigma = \mathbb{H}/K, K \subseteq \text{PSL}_2(\mathbb{R}) \).

\n
**Goal.** Understand \( \Sigma \) through \( \tilde{\Sigma} \) and \( G \).

**Fuchsian groups.** \( g \geq 2 \).

\[
\text{Aut}(\mathbb{H}) = \text{PSL}_2(\mathbb{R}) = \text{Isom}^+(\mathbb{H}, \frac{|dz|^2}{3\mathbb{I}})
\]

is hyperbolic \( \mathbb{H}, \mathbf{D} \) and \( \text{PSL}_2(\mathbb{R}) \) acts transitively on geodesics.

**Definition 2.4.5** Fuchsian groups. A Fuchsian group is a discrete subgroup of \( \text{PSL}_2(\mathbb{R}) \).

**Remark 2.4.6** (proof in book) Even if \( \Gamma \) doesn't act freely the quotient

\( \mathbb{H} \to \mathbb{H}/\Gamma \)

is still a covering map and \( \mathbb{H}/\Gamma \) is a Riemann surface.

**Reflections on \( \mathbb{H} \).** Say \( \mu \) is a geodesic in \( \mathbb{H} \), i.e. a horocycle. There is \( M \in \text{PSL}_2(\mathbb{R}) \) with \( M\mu \) the imaginary axis. Then \( R = -\bar{z} \) is the reflection over the imaginary axis. Now \( R\mu = M^{-1} \circ R \circ M \) is a reflection over \( \mu \).

\[
R\mu = \frac{a\bar{z} + b}{cz + d} \notin \text{PSL}_2(\mathbb{R})
\]

this is a problem for us.

**Triangle groups.** Given \( n, m, l \in \mathbb{Z} \cup \{\infty\} \) then there is a hyperbolic triangle with angles \( \pi/n, \pi/m, \pi/l \) if

\[
\frac{1}{n} + \frac{1}{m} + \frac{1}{l} < 1.
\]

With area \( \pi(1 - \frac{1}{n} - \frac{1}{m} - \frac{1}{l}) \).

In the disk model we can start with a wedge of the disk and by adding a choice third geodesic with endpoints on the edge we can adjust the other angles
to be what we like. So we can construct hyperbolic triangles with whatever angles we like. Then let $R_1$ be the reflection over 1 edge, $R_2$, $R_3$ similarly. By reflecting our original triangle $T$ with these reflections we can tessellate the disk, colouring alternately the triangles obtained using an odd or even number of reflections.

The only remaining problem is that $R_i$’s are not in $\text{PSL}_2(\mathbf{R})$. The solution is to define $x_1 = R_3 \circ R_1, x_2 = R_1 \circ R_2, x_3 = R_2 \circ R_3$ which are all in $\text{PSL}_2(\mathbf{R})$ now. Now we need to take the union of two adjacent triangles before as a fundamental domain, some quadrilateral that still tessellates. So we have formed a Fuchsian group from our triangles.

A presentation for this group is

$$\langle x_1, x_2, x_3 | x_1^n = x_2^m = x_3^l = 1 \rangle$$

note $n, m, l$ can still be $\infty$.

Definition 2.4.7 Triangle groups. Let $\Gamma_{n,m,l}$ be the triangle group with signature $(1/n, 1/m, 1/l)$.

Remark 2.4.8

$$\frac{1}{n} + \frac{1}{m} + \frac{1}{l} = 1$$

$$\frac{1}{n} + \frac{1}{m} + \frac{1}{l} > 1$$

still work on $\mathbf{C}$ and $\hat{\mathbf{C}}$ respectively.

Example 2.4.9 $\text{PSL}_2(\mathbf{Z})$. Consider $\Gamma_{2,3,\infty}$ angles $\pi/2, \pi/3, 0$. We can draw such a triangle in the upper half plane with vertices $i, e^{\pi i/3}, \infty$. So a fundamental domain will be the region obtained by reflecting through the imaginary axis, given by $-\frac{1}{2} \leq \Re z \leq \frac{1}{2}, |z| \geq 1$. We have $R_1 = \frac{1}{2}, R_2 = -\bar{z} + 1, R_3 = -\bar{z}$ so $x_1 = \frac{1}{z}, x_2 = \frac{1}{z + 1}, x_3 = z + 1$. Then $\Gamma_{2,3,\infty} \cong \text{PSL}_2(\mathbf{Z})$. Sometimes denoted $\Gamma(1)$.

Observation 2.4.10 If $\Gamma_1 < \Gamma_2$ and $T$ is a fundamental domain of $\Gamma_2$ then if $\gamma_1, \gamma_2, \ldots, \gamma_n \in \Gamma_2$ are representatives of $\Gamma_1 \backslash \Gamma_2$ then

$$\bigcup \gamma_i(T)$$

is a fundamental domain for $\Gamma_1$.

Example 2.4.11 $\Gamma(1)$.

$$\Gamma(2) = \{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} \} \text{ id \ (mod 2)}$$

then

$$[\Gamma(1) : \Gamma(2)] = 6$$

representatives of $\Gamma(2) \backslash \Gamma(1)$ are

$$x_1 = \text{id}, x_2 = \frac{-1}{z - 1}, x_3 = \frac{z - 1}{z}, x_4 = \frac{z - 1}{z}, x_5 = \frac{-z}{z - 1}, x_6 = \frac{-1}{z}.$$ 

Let’s see what these do, for example if $z = e^{i\theta}$

$$\Re (x_2(z)) = \frac{-1}{e^{i\theta} - 1} = \frac{-e^{i\theta} + 1}{2 - 2 \cos \theta} = \frac{1 - \cos \theta}{2 - 2 \cos \theta}$$

if we plot this we see we get two copies of a $0,0,0$ triangle so this corresponds to $\Gamma_{\infty, \infty, \infty}$.

$$\langle x_1, x_2, x_3 | x_1 x_2 x_3 = 1 \rangle = \langle x_1, x_2 \rangle = \pi_1(\mathbf{P}^1 \setminus \{0, 1, \infty\})$. 
Proposition 2.4.12 \( S_1 = H/\Gamma_1, S_2 = H/\Gamma_2 \) then
\[
S_1 \cong S_2 \iff \Gamma_1 = T \circ \Gamma_2 \circ T^{-1}, T \in \text{PSL}_2(\mathbb{R}).
\]
Proof. \( \iff \) Define an \( \phi : S_1 \to S_2 \) via \( \phi([z]_1) = [T(z)]_2. \)
\( \Rightarrow \) Take a lift
\[
\begin{array}{ccc}
H & \xrightarrow{\tilde{\phi}} & H \\
\downarrow & & \downarrow \\
H/\Gamma_1 & \xrightarrow{\phi} & H/\Gamma_2 \\
\end{array}
\]
then \( T = \tilde{\phi}. \)

Proposition 2.4.13 \( \Gamma \) a Fuchsian group acts freely
\[
\text{Aut}(H/\Gamma) = N(\Gamma)/\Gamma.
\]
Proof. Previous proposition, set \( \Gamma_1 = \Gamma_2 \)
\[
N(\Gamma) \to \text{Aut}(H/\Gamma)
\]
kernel is \( \Gamma. \)

Corollary 2.4.14 Let \( \Sigma \) be a Riemann surface with \( g \geq 2 \) then
\[
|\text{Aut}(\Sigma)| < \infty.
\]
Proof.
\[
\begin{array}{ccc}
H & \xrightarrow{\phi_1} & H/\Gamma = H/N(\Gamma) = S/\text{Aut}(S) \\
\downarrow \phi_2 & & \downarrow f \\
S = H/\Gamma & \to & \text{Aut}(\Sigma)
\end{array}
\]
since \( \phi_1, \phi_2 \) are holomorphic then so is \( f. \) So \( \text{deg } f = |N(\Gamma)/\Gamma| \) and \( \text{deg } f < \infty. \)

Say \( \Sigma, g \geq 2, G \subseteq \text{Aut}(\Sigma). \) Let \( \bar{g} \) be the genus of \( \Sigma/G \)
\[
2\bar{g} - 2 = |G|(2\bar{g} - 2) + \sum_p (I(p) - 1) = |G|(2\bar{g} - 2 + \sum_{i=1}^n (1 - \frac{1}{|I(p_i)|}))
\]
where \( I(p) \) is the stabiliser of \( p \) in \( G \) and \( \{p_i\} \) area maximal set of fixed points of \( G \) inequivalent under the action of \( G. \)

Exercise 2.4.15 \( \Sigma, g \geq 2 \) then \( |\text{Aut}(\Sigma)| \leq 84(g - 1). \) Hint: cases.

Exercise 2.4.16 Consider
\[
1 \to \Gamma(n) \to \Gamma(1) \to \text{PSL}_2(\mathbb{Z}/n\mathbb{Z}) \to 1
\]
compute genus of \( H/\Gamma(n). \)

2.5 Riemann Surfaces and Discrete Groups II (Jim)

2.5.1 Moduli space of compact Riemann surfaces with genus \( g \)
\( g = 0. \) Uniformization tells us that up to isomorphisms all Riemann surfaces of genus 0 are \( \mathbb{P}^1 \) hence the moduli space \( \mathcal{M}_0 = \{\text{pt}\}. \)
$g = 1$. Uniformization tells us that each Riemann surface of genus 1 is a torus and can be written as $\mathbb{C}/\omega_1\mathbb{Z} + \omega_2\mathbb{Z} \rightarrow \mathbb{C}/(\tau \mathbb{Z})$, with $\tau = \pm\omega_1/\omega_2$.

**Proposition 2.5.1 2.54.**

\[ \mathcal{M}_1 \cong \mathbb{H}/\text{PSL}(2,\mathbb{Z}) \cong \mathbb{C}. \]

**Proof.** Idea: Existence of

\[ C/\Lambda_{\omega_1} \sim \cong C/\Lambda_{\omega_2} \]

with $\tilde{T}(\{0\}) = \{0\}$ is equivalent to the existence of $T \in \text{Aut}(\mathbb{C})$ (choose $T(z) = wz$) such that $w(\mathbb{Z} \oplus \tau_1 \mathbb{Z}) = \mathbb{Z} \oplus \tau_2 \mathbb{Z}$. This in turn is equivalent to the existence of $A, A' \in \text{GL}_2(\mathbb{Z})$

s.t. $\det(A) = \det(A') = \pm 1$ so that

\[
\begin{pmatrix} w \\ w\tau_1 \end{pmatrix} A \begin{pmatrix} 1 \\ \tau_2 \end{pmatrix} = A' \begin{pmatrix} w \\ w\tau_1 \end{pmatrix}
\]

implies that $\tau_q = A\psi_2 = \frac{a\tau_2 + b}{c\tau_2 + d}$

and $A \in \text{PSL}_2(\mathbb{R})$. Implies $A \in \text{PSL}_2(\mathbb{Z})$ as both $\tau_1, \tau_2 \in \mathbb{H}$. Conversely if

\[ \tau_1 = \frac{a\tau_2 + b}{c\tau_2 + d} \]

isomorphism is induced by $T(z) = (c\tau_2 + d)z$. $\blacksquare$

$g > 1 \mathcal{M}_g$ is a complex variety of dimension $3g - 3$. Uniformization tells us that describing a Riemann surface amounts to specifying $2g$ real $2 \times 2$ matrices \( \{\gamma_i\}_{i=1}^{2g} \) such that

1. $\det(\gamma_i) = 1$ which implies that $\gamma_i$ depends on 3 real parameters so we have a total of $6g$.

2. $\prod_{i=1}^{g} [\gamma_i, \gamma_{g+i}] = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$ 3 relations, so $6g - 3$. Since for any $\gamma \in \text{PSL}_2(\mathbb{R})$

\[ \Gamma = \langle \gamma_i \rangle \] and $\gamma \Gamma \gamma^{-1}$ uniformize isomorphic Riemann surfaces implies $6g - 6$ real parameters, so $3g - 3$ complex parameters.

### 2.5.2 Monodromy

Let $f : S_1 \rightarrow S$ be a morphism of degree $d$ ramified over $y_1, \ldots, y_n \in S$. For $y \in S \setminus \{y_1, \ldots, y_n\}$ we have a group homomorphism

\[ M_f : \pi_1(S \setminus \{y_1, \ldots, y_n\}) \rightarrow \text{Bij}(f^{-1}(y)) \]

$\gamma \mapsto M_f(\gamma) = \sigma_{\gamma}^{-1}$.

$\sigma_\gamma$ is defined as follows:

$\gamma \in \pi_1(S \setminus \{y_1, \ldots, y_n\})$

lifts to a path $\tilde{\gamma}$ from $x \in f^{-1}(y)$ to another $x' \in f^{-1}(y)$ set $\sigma_\gamma(x) = x'$. If we number the points in $f^{-1}(y)$ we may think of $M_f(\pi_1) \subseteq \Sigma_d$, via some $\phi : \{1, \ldots, d\} \rightarrow f^{-1}(y)$. Mon($f$) is the image of $M_f(\pi_1)$ in $\Sigma_d$. 
Monodromy and Fuchsian groups. Let 
\[ \pi : \mathbb{H}/\Gamma_1 \to \mathbb{H}/\Gamma \]
be the Fuchsian group representation of the map 
\[ f : S_1 \to S \ni y. \]
Identifications \[ y = [z_0]_\Gamma \] for some \( z_0 \in \mathbb{H} \).
\[ \pi_1(S \setminus \{y_1, \ldots, y_n\}) \cong \Gamma \]
\[ f^{-1}(y) = \{[\beta z_0]_\Gamma \} \]
where \( \beta \) runs along a set of representatives of \( \Gamma_1 \setminus \Gamma \).
\[ M_f : \Gamma \to \text{Bij}(\Gamma_1 \setminus \Gamma) \]
\[ \gamma \mapsto M_f(\gamma) \]
\[ \implies \gamma \sim \pi_1([z_0, \gamma(z_0)]) \]
where \([z_0, \gamma(z_0)]\) is a path in \( \mathbb{H} \). Lift this loop to \( \mathbb{H}/\Gamma_1 \) is the path \( \pi\Gamma_1(\beta[z_0, \gamma_0(z_0)]) \).
which corresponds to \( \Gamma_1 \beta \gamma \), this implies \( \sigma_\gamma(\Gamma_1 \beta) = \Gamma_1 \beta \gamma \).

Corollary 2.5.2 2.59.

\[ M_\pi : \Gamma \to \text{Bij}(\Gamma_1 \setminus \Gamma) \]
\[ \text{induces an isomorphism} \]
\[ \bigcap_{\beta \in \Gamma_1} \beta^{-1} \Gamma_1 \beta \cong \text{Mon}(\pi) \]
\[ \text{characterize morphisms by monodromy. Let } f_i \text{ have degree 2, non conjugate.} \]

**Proposition 2.5.3 2.63.** For \( S \) a compact Riemann surface and \( \beta = \{a_1, \ldots, a_n\} \subset S \) for some \( d \geq 1 \) there are only finitely many pairs \((\tilde{S}, f)\) where \( \tilde{S} \) is a compact Riemann surface and
\[ f : \tilde{S} \to S \]
is a degree \( d \) morphism with branching value set \( \beta \).

**Proof.** Special case: Assume \( S = \mathbb{P}^1 \) and \( n = 3 \).
\[ \Gamma = \Gamma(2) = \{A \in \text{PSL}_2(\mathbb{Z}) : A = \text{id} \pmod{2}\} \]
\[ = \pi_1(S' \setminus \{0, 1, \infty\}) \]
is generated by \( \gamma_1, \gamma_2 \) so any map \( M_f : \Gamma(2) \to \Sigma_d \) is determined by images of \( \gamma_1, \gamma_2 \).
\[ \blacksquare \]

**2.5.3 Galois coverings**

**Definition 2.5.4** A covering \( f : S_1 \to S_2 \) is Galois (or regular, or normal) if the covering group
\[ \text{Aut}(S, f) = \{h \in \text{Aut}(S_1) : f \circ h = f\} = G \]
acts transitively on each fibre. With this notion we can think of \( S_1 \to S_1/G \). \( \diamond \)
Proposition 2.5.5. \( f : S_1 \to S_2 \) is Galois if and only if \( f^* : M(S_2) \to M(S_1) \) is a Galois extension. In this case \( \text{Aut}(S_1, f) \cong \text{Gal}(M(S_1)/M(S_2)) \).

Example 2.5.6. Hyperelliptic covers of \( \mathbb{P}^1 \) given by
\[
S = \{ y^2 = \prod_{i=1}^N (x-a_i) \} \to \mathbb{P}^1
\]
covering group \( G \) is order 2 generated by the involution \( J(x, y) = (x, -y). \) \( \square \)

Proposition 2.5.7. A covering \( f : S_1 \to S_2 \) is normal/Galois iff \( \deg(f) = |\text{Mon}(f)| \).

2.5.4 Normalization of coverings of \( \mathbb{P}^1 \)

Let \( f : S \to \mathbb{P}^1 \) be a cover of \( \deg d > 0 \) with \( \text{Mon}(f) \leq \Sigma_d \).

The normalisation \( \tilde{f} : \tilde{S} \to \mathbb{P}^1 \) associated to \( f \) has \( \text{Mon}(f) \cong \text{Aut}(\tilde{S}, \tilde{g}) \) and \( f^* : M(\mathbb{P}^1) \to M(S) \) is the normalisation of the extension
\[
f^* : M(\mathbb{P}^1) \hookrightarrow M(S)
\]

Normalization of extensions \( K \to L \) is a Galois extension of \( K \) of lowest possible degree containing \( L \).

Definition 2.5.8. Normalization of \( f : S \to \mathbb{P}^1 \) \( \deg d > 0 \) is a Galois covering \( \tilde{f} : \tilde{S} \to \mathbb{P}^1 \) of lowest possible degree s.t. \( \exists \pi : \tilde{S} \to S \) with the diagram commuting. \( \diamond \)

Corollary 2.5.9. \( \text{Mon}(f) \cong \text{Aut}(\tilde{S}, \tilde{f}) \)

Interpretation in terms of Fuchsian groups:

Proposition 2.5.10. Let \( f : S_1 \to S \) be a covering of Riemann surfaces \( S_1 \setminus f^{-1}\{y_1, \ldots, y_n\} \to S \setminus \{y_1, \ldots, y_n\} \). The unramified cover and \( \pi : \mathbb{H}/\Gamma_1 \to \mathbb{H}/\Gamma \) the Fuchsian group representatives. The normalisation of \( f \) can be represented as the compactification of
\[
\mathbb{H}/\bigcap_{y \in \Gamma} y^{-1}\Gamma_1 y \to \mathbb{H}/\Gamma_1 \to \mathbb{H}/\Gamma
\]
so the covering group is isomorphic to \( \Gamma/\bigcap \gamma^{-1}\Gamma_1 \gamma \cong \text{Mon}(f) \).

Example 2.5.11. Let \( F(x, y) = y^2 x - (y - 1)^3 \) consider
\[
S_F \to \mathbb{P}^1
\]
\[
(x, y) \to x
\]
$S_F$ has genus 0. $S_F \to \mathbb{P}^1$ is of degree 3 and ramified at most over $0, -\frac{27}{4}, \infty$. 
$\text{Mon}(x) = \Sigma_3$ so not a normal covering. Normalization of $(S_F, x)$ is $\tilde{S}_F, \tilde{x})$ where
$$\tilde{F}(x, y) = y^2(1 - y)^2x + (1 - y + y^2)$$

### 2.6 Belyi’s theorem (Maria)

**Theorem 2.6.1** Let $S$ be a compact Riemann surface, then the following are equivalent.

1. $S$ is defined over $\overline{\mathbb{Q}}$ (iff over a number field)
2. $S$ admits a morphism $f : S \to \mathbb{P}^1$ with at most 3 branching values.

**Definition 2.6.2 Belyi functions.** A meromorphic function with less than 4 branching values is a Belyi function. ♦

**Remark 2.6.3**
1. Branching values can be taken to be in $\{0, 1, \infty\}$.
2. If $S \neq \mathbb{P}^1$, then $f : S \to \mathbb{P}^1$ has at least 3 branching values.

**Definition 2.6.4 Belyi polynomials.** Let $m, n \in \mathbb{N}$, $\lambda = m/(m + n)$, define
$$P_\lambda(x) = P_{m, n}(x) = \frac{(m + 1)^{m+n}}{m^{m+n}}x^m(1 - x)^n$$

**Belyi polynomials.** ♦

**Proposition 2.6.5** $P_\lambda$ satisfies

1. $P_\lambda$ ramifies at exactly $0, 1, \lambda, \infty$.
2. $P_\lambda(0) = P_\lambda(1) = 0, P_\lambda(\lambda) = 1, P_\lambda(\infty) = \infty$.

**Example 2.6.6**
$$S_\lambda : y^2 = x(x - 1)(x - \lambda)$$
with $\lambda = m/(m + n)$. From ex. 1.32
$$x : S_\lambda \to \mathbb{P}^1$$
$$(x, y) \mapsto x$$
$$\infty \mapsto \infty$$
ramifies over $0, 1, \lambda, \infty$. Then $f = P_\lambda \circ x : S_\lambda \to \mathbb{P}^1$ ramifies exactly at $(0, 0), (1, 0), (\lambda, 0), \infty$. With branching values $0, 1, \infty$ so that $f$ is a Belyi function. ♦

#### 2.6.1 Proof of a) implies b)

**Note 2.6.7** It’s enough to show $\exists f : S \to \mathbb{P}^1$ ramified over $\{0, 1, \infty, \lambda_1, \ldots, \lambda_n\} \subseteq \mathbb{Q} \cup \{\infty\}$. Given this we can repeatedly use Belyi polynomials to obtain $g : S \to \mathbb{P}^1$ ramified over $\{0, 1, \infty\}$.

Write $S = S_F$
$$F(x, y) = p_0(x)y^n + \cdots + p_n(x)$$
defined over $\overline{\mathbb{Q}}[x, y]$. Let $B_0 = \{\mu_1, \ldots, \mu_s\}$ be the branching values of $x : S_F \to \mathbf{P}^1$.

Theorem 1.86 says that the each $\mu_i$ is $\infty$, a root of $p_i(x)$ or a common root of $F, F_i$ which implies by lemma 1.84 that $B_0 \subseteq \overline{\mathbb{Q}} \cup \{\infty\}$. If $B_0 \subseteq \mathbb{Q} \cup \{\infty\}$ we are done otherwise let $m_1(T) \in \mathbb{Q}[T]$ be the minimal polynomial of $\{\mu_1, \ldots, \mu_s\}$. Let $\{\beta_1, \ldots, \beta_d\}$ be the roots of $m'_1(T)$ and $p'(T)$ their min. poly. Note : $\deg P(t) < \deg m'_1(T)$

Note: $\text{Branch}(g \circ f) = \text{Branch}(g) \cup g(\text{Branch}(f))$ branching values.

So $B_1 \xrightarrow{\text{Branch}(m_1 \circ x)} m_1(\{\text{roots of } m'_1\}) \cup \{0, \infty\}$.

$$S \xrightarrow{\psi} \mathbf{P}^1 \xrightarrow{m_1} \mathbf{P}^1$$

If $B_1 \subseteq \mathbb{Q} \cup \{\infty\}$ done. Otherwise let $m_2(T)$ be the minimal polynomial /$\mathbb{Q}$ of $\{m_1(\beta_1), \ldots, m_1(\beta_d)\}, B_2 = \text{Branch}(m_2 \circ m_2 \circ x)$. Fact: $\deg(m(t)) < \deg(m_1(T))$.

Repeat inductively until $B_k \subseteq \mathbb{Q} \cup \{\infty\}$ which is guaranteed by the decreasing degrees.

2.6.2 Algebraic characterization of morphisms

Proposition 2.6.8 Defining a morphism $f : S_F \to S_G$ is equivalent to giving a pair of rational functions

$$f = (R_1, R_2), \quad R_i = \frac{P_i}{Q_i}, \quad P_i, Q_i \in \mathbb{C}[x, y], \quad Q_1 \neq (F)$$

such that $Q_1^{\deg(G)} Q_2^{\deg(G)} G(R_1, R_2) = H F$ for some $H \in \mathbb{C}[x, y]$. $f(R_1, R_2)$ is an isomorphism if there exists an inverse morphism $h : S_G \to S_F$.

Remark 2.6.9

$$\xymatrix{ S_f \ar[r]^f \ar[d]_m & S_G \ar[d]^h \cr S_D & \ar[l]^\Psi \cr}$$

The fact that this diagram commutes can be expressed by polynomial identities.

2.6.3 Galois action

Let $\text{Gal}(\mathbb{C}) = \text{Gal}(\mathbb{C}/\mathbb{Q})$.

Definition 2.6.10 For $\sigma \in \text{Gal}(\mathbb{C})$, $a \in \mathbb{C}$ denote $a^\sigma = \sigma(a)$,

1. If $P = \sum a_{ij} x^i y^j \in \mathbb{C}[x, y]$ set

$$P^\sigma = \sum a_{ij}^\sigma x^i y^j \in \mathbb{C}[x, y]$$

if $R = P/Q$ set $R^\sigma = P^\sigma/Q^\sigma$.

2. If $S \simeq S_F, S^\sigma = S_{F^\sigma}$.

3. If $\Psi = (R_1, R_2) S_F \to S_G$ is a morphism, set $\Psi^\sigma = (R_1^\sigma, R_2^\sigma) : S_{F^\sigma} \to S_{G^\sigma}$.

4. For an equivalence class $(S, f) = (S_F, R(x, y))$ of ramified covers of $\mathbf{P}^1$ set $(S, f)^\sigma = (S^\sigma, f^\sigma) = (S_{F^\sigma}, R^\sigma(x, y))$. 

$\diamondsuit$
Exercise 2.6.11 Verify this Galois action is well-defined (lemma 3.12).

Recall: $S_F$ is constructed from a noncompact Riemann surface $S_F^\infty \subseteq \mathbb{C}^2$ by adding finitely many points, (theorem 1.86). If $P = (a, b) \in S_F^\infty$ then $P^\sigma = (a^\sigma, b^\sigma)$. What about the other points?

2.6.4 Points and valuations

Definition 2.6.12 Let $M$ be a function field. A (discrete) valuation of $M$ is $v: M^* \rightarrow \mathbb{Z}$ s.t.

1. $v(\phi \psi) = v(\phi) + v(\psi)$
2. $v(\phi \pm \psi) \geq \min\{v(\phi), v(\psi)\}$
3. $v(\phi) = 0$ if $\phi \in \mathbb{C}^*$
4. $v$ is nontrivial $\exists \phi: v(\phi) \neq 0$

set $v(0) = \infty$.

Facts:

$A_v = \{\phi \in M : v(\phi) \geq 0\} \subseteq M$

is a subring that is a local ring with a maximal ideal $M_v = \{\phi \in M : v(\phi) > 0\} = (\phi)$ for some $\phi$ a uniformizer.

If $v(\phi) = 1$ $v$ is normalised.

Proposition 2.6.13 3.15. Every point $P \in S$ a compact Riemann surface defines a valuation on $M(S)$ by $v_P(\phi) = \text{ord}_P(\phi)$.

Proof. Easy exercise. ■

Theorem 2.6.14 3.23. For any compact Riemann surface $S$

$$P \in S \mapsto v_P = \text{ord}_P$$

gives a 1-1 correspondence between points of $S$ and normalised valuations on $M(S)$.

Proof. Sketch: First prove it for $S = \mathbb{P}^1$.

Inductively meromorphic functions separate points.

Surjectivity study behaviour of valuations in finite extensions of fields and use a nonconstant morphism $f: S \rightarrow \mathbb{P}^1$ to reduce to the case of $\mathbb{P}^1$. ■

Galois action on points. Definition 2.6.15

1. Given a valuation $v$ on $M(S)$ define a valuation $v^\sigma$ on $M(S^\sigma)$ by $v^\sigma = v \circ \sigma^{-1}$ i.e. $v^\sigma(\psi^\sigma) = v(\psi)$ for all $\psi \in M(S)$.
2. For $P \in S$ define $P^\sigma \in S^\sigma$ as the unique point in $S^\sigma$ s.t. $v_{P^\sigma} = (v_P)^\sigma$.

Proposition 2.6.16 3.25.

1. For $\sigma \in \text{Gal}(\mathbb{C})$, $P \mapsto P^\sigma$ is a bijection $S \rightarrow S^\sigma$.
2. On $P \in S_F^\infty$ this agrees with the previous definition of $P^\sigma$.
3. $a^\sigma = a$ for all $a \in \mathbb{Q} \cup \{\infty\}$ for all $\sigma \in \text{Gal}(\mathbb{C})$.

Proof. Sketch

1. $a \mapsto a^\sigma^{-1}$. 

}$
2. Follows as in proof of 3.22
3. Obvious for \(a \in \mathbb{Q}\), for \(\infty\):
\[
(v_\infty)^a(x - 1) = v_\infty(x - a^{-1}) = 1 = v_\infty(x - 1)
\]
for all \(a \in \mathbb{C}\) implies \((v_\infty)^{a^{-1}} = v_\infty\) implies \(\infty^a = \infty\).

\[\blacksquare\]

### 2.6.5 Elementary invariants of the action of \(\text{Gal}(\mathbb{C})\).

**Remark 2.6.17** The bijection \(S \leftrightarrow S^\sigma\) is not holomorphic. In general \(S\) and \(S^\sigma\) are not isomorphic.

**Theorem 2.6.18** The action of \(\text{Gal}(\mathbb{C})\) on pairs \((S, f)\) satisfies
1. \(\deg(f^\sigma) = \deg(f)\)
2. \((f(P))^\sigma = f^\sigma(P^\sigma)\)
3. \(\text{ord}_{P^\sigma}(f^\sigma) = \text{ord}_P(f)\)
4. \(a \in \hat{\mathbb{C}}\) is a branching value of \(f\) iff \(a^\sigma\) is a branching value of \(f^\sigma\).
5. \(\text{genus}(S) = \text{genus}(S^\sigma)\) i.e. they are homeomorphic.
6. \(\text{Aut}(S, f) \rightarrow \text{Aut}(S^\sigma, f^\sigma)\) via \(h \mapsto h^\sigma\) is a group homomorphism.
7. The monodromy group \(\text{Mon}(f)\) of \((S, f)\) is isomorphic to \(\text{Mon}(f^\sigma)\) of \((S^\sigma, f^\sigma)\).

We will use properties 1 and 4 at least.

**Proposition 2.6.19** **Criterion 3.29.** For a compact Riemann surface \(S\) the following are equivalent

1. \(S\) is defined over \(\overline{\mathbb{Q}}\).
2. \(\{S^\sigma\}_{\sigma \in \text{Gal}(\mathbb{C})}\) contains only finitely many isomorphism classes of Riemann surfaces.

**Proof.** 1 implies 2: \(S = S_F, F = K[x, y]\) for \(K\) a number field then
\[
|\{F^\sigma\}_{\sigma \in \text{Gal}(\mathbb{C})}| \leq [K : \mathbb{Q}]
\]
2 implies 1 is section 3.7.

**Proof of b implies a in Belyi’s theorem (3.61).** Suppose \(f: S \rightarrow \mathbb{P}^1\) is a morphism of degree \(d\) with branching values \(\{0, 1, \infty\}\). By theorem 3.28 \(\forall \sigma \in \text{Gal}(\mathbb{C})\)
\[
f^\sigma: S^\sigma \rightarrow \mathbb{P}^1
\]
is a morphism of degree \(d\) and branching values are
\[
\{\sigma(0), \sigma(1), \sigma(\infty)\} = \{0, 1, \infty\}.
\]
So \(\{f^\sigma\}_{\sigma \in \text{Gal}(\mathbb{C})}\) gives rise to only finitely many monodromy homomorphisms.
\[
F_{f^\sigma}: \pi_1(\mathbb{P}^1 \setminus \{0, 1, \infty\}) \rightarrow \Sigma_d
\]
the fundamental group is free on two generators so there are only finitely many such maps. Theorem 2.61 implies \( \{ S^g \}_{g \in \text{Gal}(C)} \) contains only finitely many equivalence classes so by the criterion \( S \) is defined over \( \overline{\mathbb{Q}} \).

2.6.6 The field of definition of Belyi functions (3.8)

**Proposition 2.6.20** Belyi functions are defined over \( \overline{\mathbb{Q}} \).

*Proof.* Use the same methods as in 3.7. \( \blacksquare \)

2.7 Dessins (Berke)

**Definition 2.7.1** A dessin is a pair \( (X, D) \) where \( X \) is an oriented compact topological surface and \( D \subset X \) is a finite graph:

1. \( D \) is connected
2. \( D \) is bicoloured
3. \( X \setminus D \) is a disjoint union of topological disks.

Not all of these are so important (for example 3 implies 1 (but the converse does not hold)). We can also obtain a bicoloured graph from an uncoloured graph by subdividing all edges and colouring the new vertices black and the others white.

A single edge in a sphere is, a single edge in a torus is not.

**Permutation representation of a Dessin.** Label the edges of a dessin \( \{1, \ldots, N\} \) then

\[
\sigma_0(i) = \text{subsequent edge in the cycle around the white vertex of } i
\]
as we have a positive orientation on the edges

\[
\sigma_1(i) = \text{subsequent edge in the cycle around the black vertex of } i.
\]

Then we define

**Definition 2.7.2** \( (\sigma_0, \sigma_1) \) is the permutation representation pair of \( (X, D) \).

Say

\[
\sigma_0 = (1, \ldots, N_1)(N_1 + 1, \ldots, N_2)\cdots
\]
a product of disjoint cycles. Then each of these cycles corresponds to a white vertex, where the length of the cycle is the degree of the corresponding vertex. Same for \( \sigma_1 \) and black vertices.

\[
\{\text{cycles appearing in the decomposition of } \sigma_0\sigma_1\}
\]

\[
\downarrow
\]

\[
\{\text{faces of } D\}.
\]
Exercise 2.7.3 Prove this.

Remark 2.7.4 $D$ connected implies that $\langle \sigma_0, \sigma_1 \rangle$ is transitive on $\Sigma_N$. As $D$ is bicoloured the cycles on $D$ contain an even number of edges.

A dessin is not a triangulation of $X$ but

$$\chi(X) = \#V - \#E + \#F$$

proof later.

Proposition 2.7.5

$$\chi(X) = (\#cycles of \sigma_0 + \#cycles of \sigma_1) - N + \#\{cycles of \sigma_0 \sigma_1\}.$$

$$(\sigma_0, \sigma_1) \leadsto (X', D)$$

$$\langle \sigma_0, \sigma_1 \rangle \subseteq \Sigma_N$$

is transitive.

Proposition 2.7.6 There exists $(X, D)$ with permutation representation $(\sigma_0, \sigma_1)$.

Proof. Write $\sigma_0 \sigma_1 = \tau_1 \cdots \tau_k$, $\tau_i$ disjoint cycles each of length $n_i$ with $\sum n_i = N$. Create $k$ faces bounded by $2n_1, \ldots, 2n_k$ vertices, and assign the vertices white and black colours so that the graph is bicoloured. As $\sigma_0 \sigma_1$ should jump two each time we get an identification of all edges which we then glue using $\sigma_0$. ■

Definition 2.7.7 We say that

$$(X_1, D_1) \sim (X_2, D_2)$$

if there exists an orientation preserving homeomorphism $\phi: X_1 \to X_2, \phi|_{D_1}: D_1 \to D_2$.

Theorem 2.7.8

$$\{\text{Dessins}\}/\sim \leftrightarrow \{(\sigma_0, \sigma_1), \langle \sigma_0, \sigma_1 \rangle \subseteq \Sigma_N \text{ transitive}\}/\sim$$

2.7.2 Dessins 2 Belyi pairs

Triangle decomposition of $(X, D) \leadsto T(D)$ a set of triangles that cover $D$ and intersect along edges or at vertices.

Example 2.7.9 Edge in the sphere, add an extra vertex $\times$ not on the edge and get a decomposition into two triangles. □

We will label triangles by $T_j^\pm$ as there are two for each edge, by orientation some are the same.

$$T(D) \leadsto f_D: X \to \hat{C}$$

Glue

$$f_j^\pm: T_j^\pm \to \overline{\mathbb{H}}^2$$

for $? \in \{+,-\}$, where $f_j^+ = f_j^-$ on the intersection. Where $\partial T_j \to \mathbb{R} \cup \{\infty\}$

black $\mapsto 0$

white $\mapsto 1$

$\times \mapsto \infty$
and we have $\text{Branch}(f_D) \subseteq \{0, 1, \infty\}$. Now $\deg f_D = \# \text{edges of } D$, $m_v(f_D) = \deg v$, $f_D^{-1}([0, 1]) = D$. Modify $X$ a little bit and use some lemma to get $S_D \cong_{\text{top}} X$ for some Riemann surface with $f_D: S_D \rightarrow \mathbb{P}^1$.

**Definition 2.7.10** $(S, f)$ is a Belyi pair with $S$ compact Riemann surface and $f$ a Belyi function on $S$.

$$(S_1, f_1) \sim (S_2, f_2)$$

if it is an isomorphism of ramified coverings. 

So we can now go in both directions.

$$\{\text{Dessins}\} \sim \uparrow \{\text{Belyi pairs}\}$$

$$(X, D) \mapsto (S_D, f_D)$$

$$(S, D) \leftarrow (S, f)$$

Now to define the Galois action

$$G_Q \cup \{\text{Dessins}\} \leftrightarrow \{\text{Belyi pairs}\}$$

$$(X, D) \sim \sigma \mapsto (X, D)_{\sigma}$$

$$(S_D, f_D) \mapsto (S_D^\sigma, f_D^\sigma)_{\sigma}$$

The $G_Q$ action is faithful on dessins of genus $g$.

**Example 2.7.11** Same example $\mathbb{P}^1$ with a single edge, $f_D = z$, $\deg f_D = \# \text{edges}$, $m_v(f) = \deg v$. 

**Exercise 2.7.12** String.

**Exercise 2.7.13** $n$ star.

## 2.8 A Sandwich Table of Dessins d’Enfants

Alex: So I haven’t typed this section as it was a lot of pictures and I haven’t got nice scans of them, will try at some point (maybe?). Angus’ notes can be found at [http://math.bu.edu/people/angusmca/buntes/spring2018.html](http://math.bu.edu/people/angusmca/buntes/spring2018.html).

## 2.9 Belyi’s theorem, effective Mordell and ABC (Angus)

We begin with one of the most famous results in arithmetic geometry.

**Theorem 2.9.1** Mordell conjecture/Falting’s theorem. Let $C$ be an algebraic curve of genus $\geq 2$ over a number field $K$. Then $C(K)$ is finite.

There are many proofs of this, Falting’s being the original and most famous.

**Remark 2.9.2** Falting’s proof is not effective. That is, it cannot predict the number of points or give any bounds.

Today we’ll show how this theorem follows from a (much harder conjecture), but how this nonetheless gives new insight into the question of effectiveness. Specifically we’ll show ABC implies Mordell.
“Mordell is as easy as ABC” - Zagier

**Conjecture 2.9.3 ABC.** Let \( A, B, C \in \mathbb{Z} \) s.t. \( \gcd(A, B, C) = 1 \) and \( A + B + C = 0 \), then for all \( \epsilon > 0 \) there exists a constant \( k_\epsilon \) s.t.

\[
N(A, B, C) > k_\epsilon H(A, B, C)^{1-\epsilon}
\]

where

\[
N(A, B, C) = \prod_{p|ABC} p
\]

\[
H(A, B, C) = \max(|A|, |B|, |C|).
\]

This is a remarkably deep statement about the integers. Something surprising about how one compares the additive and multiplicative structures of the integers.

For our purposes (to connect it to the curves and Mordell) we’d like to remove the dependence on integrality and coprimality, by making it scaling invariant.

We now define

\[
H(A, B, C) = \prod_{v} \max(|A|_v, |B|_v, |C|_v)
\]

\[
N(A, B, C) = \prod_{p \in I} p
\]

for

\[
I = \{ p \text{ prime} : \max(|A|_p, |B|_p, |C|_p) > \min(|A|_p, |B|_p, |C|_p) \}.
\]

**Exercise 2.9.4** For sanity.

\[
H(\lambda A, \lambda B, \lambda C) = H(A, B, C)
\]

\[
N(\lambda A, \lambda B, \lambda C) = N(A, B, C)
\]

for \( \lambda, A, B, C \in \mathbb{Q}^\times \). Moreover if \( A, B, C \in \mathbb{Z} \) and \( \gcd = 1 \) then we recover the original definition.

Since we have \( A + B + C = 0 \) and our functions are scaling invariant, they only depend on \( r = -A/B \). We’ll also reformulate it over an arbitrary number field \( K \).

Note that to satisfy the hypotheses of the conjecture we require

\[
r \in \mathbb{P}_K \setminus \{0, 1, \infty\}.
\]

We now define

\[
H(r) = \prod_{v} \max(1, |r|_v)
\]

\[
N(r) = \prod_{p \in I} p
\]

for

\[
I = \{ p \text{ prime} : \max(v_p(r), v_p(1/r), v_p(r-1)) > 0 \}.
\]

**Remark 2.9.5** In fact this new height is off from the old one by a constant factor, but since ABC allows for a constant factor this won’t trouble us.
Motivation: ABC implies Fermat bound. One can see this simply by assuming a solution
\[ x^n + y^n = z^n, \quad n \geq 3 \]
and setting
\[ (A, B, C) = (x^n, y^n, z^n) \]
then
\[ N(A, B, C) = \prod_{p \mid ABC} p \leq |xyz| < \max(|x|^3, |y|^3, |z|^3) = H(A, B, C)^{3/n}. \]
So setting
\[ \epsilon = 1 - 3/n \]
for \((A, B, C)\) s.t. \(H(A, B, C)\) is sufficiently large we get a contradiction to ABC. Thus ABC gives us a bound on the possible solutions to the Fermat equation, reducing the remainder of the conjecture to a finite computation.

Let us phrase this in the following alternate way: Let
\[ F_n : x^n + y^n + z^n = 0 \]
be the Fermat curve and consider the function
\[ f : F_n \to \mathbb{P}^1 \]
\[ (x: y: z) \mapsto -\left(\frac{x}{y}\right)^n \]
ramified over 0, 1, \(\infty\).

Note 2.9.6 \(\deg(f) = n^2\)
Each of 0, 1, \(\infty\) has \(n\) preimages in \(F_n(\overline{\mathbb{Q}})\).

The idea now is that \(N(A, B, C)\) is measuring ramification, while \(H(A, B, C)\) is a height function. The note above tells us that each of 0, 1, \(\infty\) contributes a factor of \(O(H(A, B, C)^{n/n^2})\) to \(N(A, B, C)\). So in this formulation, what we used was the existence of a rational function \(f\) such that
\[ \#\{p \in C(\overline{\mathbb{Q}}) : f(p) \in \{0, 1, \infty\}\} < \deg(f). \]

Exercise 2.9.7 If \(C\) has genus 0 or 1, no such \(f\) can exist (hint: Riemann-Hurwitz).

ABC implies a bound on Mordell. We begin with a technical proposition:

Proposition 2.9.8 Let \(K\) be a number field and \(C/K\) a curve. Let \(f \in K(C)\) be a rational function of degree \(d\). Then for \(p \in C(K) \setminus f^{-1}(0)\) we have
\[ \log N_0(f(p)) < (1 - b_f(0)/d) \log H(f(p)) + O(\sqrt{\log H(f(p)) + 1}) \]
with the following notation
\[ N(r) = N_0(r)N_1(r)N_\infty(r) \]
\[ N_0(r) = \prod_{\nu \geq (r)} \text{Norm}(\nu) \]
\[ N_1(r) = \prod_{\nu \geq (1-r)} \text{Norm}(\nu) \]
\[ N_{\infty}(r) = \prod_{p \geq (1/r)} \text{Norm}(p) \]

\[ b_f(0) = \sum_{f(p) = 0} (e_p - 1). \]

**Proof.** The genus 0 case follows from the fact that the \( f \) is a rational function (and in fact the error term is \( O(1) \)) (exercise). For the general case we need the theory of log heights on curves. From this we require the following

- For \( D \) a divisor on \( C \) we have a height function
  \[ h_D(\cdot) \]
  which is well defined up to \( O(1) \).

- If \( D = \sum m_k D_k \)
  is a decomposition into irreducible divisors, then
  \[ h_D(P) = \sum m_k h_{D_k}(P). \]

- For \( \Delta \) a degree 0 divisor
  \[ h_\Delta(P) = O(\sqrt{\log H(f(P))} + 1). \]

Let \( D = \text{div}_0(f) = \sum m_k D_k, D' = \sum_{f(p) = 0} (P) \) then \( b_f(0) = \deg D' \). Then

\[ \log H(f(P)) = h_D(P) + O(1) = \sum m_k h_{D_k}(P) + O(1) \]

since \( \log H(f(P)) \) is also a height function relative to \( D \). We now turn to \( N_0(f(P)) \). Any prime occurring in this must also occur in \( h_{D_k}(P) \) for some \( k \) (except for a finite set \( \{p : p | f \text{ or } p \text{ bad red. for } C\} \)). Then

\[ N_0(f(P)) < \sum h_{D_k}(P) + O(1) = h_{D'}(P) + O(1). \]

Letting

\[ \Delta = (\deg D)D' - (\deg D')D \]

we have

\[ h_\Delta(P) = O(\sqrt{\log H(f(P))} + 1) \]

thus

\[ \log N_0(f(P)) < h_{D'}(P) + O(1) \]

\[ = \frac{1}{\deg D}(\deg D')h_{D'}(P) + O(1) \]

\[ = \frac{1}{\deg D}(\deg D')h_D(P) + O(\sqrt{\log H(f(P))} + 1) \]

\[ = \frac{1 - b_f(0)}{d} \log H(f(P)) + O(\sqrt{\log H(f(P))} + 1) \]

\[ \blacksquare \]

**Remark 2.9.9** One can show the above for \( N_1, N_\infty \) instead making the appropriate replacements for \( f \).
Adding the three terms together we get
\[
\log N_0(f(P))N_1(f(P))N_\infty(f(P)) < \left( \frac{1 - \frac{b_f(0)}{d}}{d} + \frac{1 - \frac{b_f(1)}{d}}{d} + \frac{1 - \frac{b_f(\infty)}{d}}{d} \right) \log H(f(P)) + O(\cdots)
\]
\[
\log N(f(P)) < \frac{1}{d} \left( \#f^{-1}(0) + \#f^{-1}(1) + \#f^{-1}(\infty) \right) \log H(f(P)) + O(\cdots)
\]
\[
< \frac{m}{d} \log H(f(P)) + O(\cdots)
\]
where
\[
m = \#\{P \in C(\overline{\mathbb{Q}}) : f(P) \in \{0, 1, \infty\}\}
\]
exponentiating we get
\[
N(f(P)) < H(f(P))^{m/d}K.
\]

**Theorem 2.9.10 ABC implies Mordell.** *ABC implies Mordell.*

**Proof.** Let \( C \) be a given curve of genus \( g \geq 2 \) Belyi’s theorem gives a function \( f : C \rightarrow \mathbb{P}^1 \) ramified over \( \{0, 1, \infty\} \). By Riemann-Hurwitz \( m = d + 2 - 2g, \) \( d = \deg(f) \) \( m \) as above. Thus \( m < d \), thus we can pick \( 0 < \epsilon < 1 - \frac{m}{d} \) and so for sufficiently large \( H(f(P)) \) (i.e. all but finitely many) we have a counterexample to ABC. ■

**Remark 2.9.11 Closing remarks.** Belyi’s theorem gives an algorithm for determining \( f : C \rightarrow \mathbb{P}^1 \) i.e. it is effective.

One can also show ABC implies Siegel’s theorem.

In fact it can be shown that a particular effective form of Mordell (applied to \( y^2 + y = x^5 \)) for all number fields implies ABC. This is related to Szpiro’s conjecture.

**2.10 Dessins, integer points on elliptic curves and a proof of the ABC conjecture (Alex)**

**2.10.1 A proof of the ABC theorem (for polynomials)**

Last week Angus told us about the incredibly powerful ABC conjecture and its arithmetic consequences (apparently). This week we will prove this conjecture (for polynomials). The proof is very similar to some of the things Angus mentioned, but seeing as I wasn’t there its new to me... Following Goldring / Stothers / Parab.

Let \( K \) be algebraically closed of characteristic 0, with \( f \in K[\! [x] \! ] \), we can define the radical as before
\[
\text{rad}(f) = \prod_{p \mid f} p
\]
over the primes/irreducibles dividing \( f \), this is the maximal squarefree polynomial dividing \( f \). How do we measure the size of a polynomial? Let
Chapter 2. Dessins D’Enfants

\( r(f) = \deg \text{rad}(f) \), and \( h(f_1, \ldots, f_n) = \max\{\deg f_i\} \). This is a complicated way of saying
\[
\#\{x \in K : f(x) = 0\},
\]
but we do so to emphasise the link with ABC.

The result is then

**Theorem 2.10.1 Mason-Stothers.** Let

\[ e, f, g \in K[x], \; e + f = g \]

be pairwise coprime and all of height \( > 0 \). Then

\[ h(e, f, g) < r(efg) = r(e) + r(f) + r(g). \]

We have sharpness if and only if \( f/g \) is a Belyi map for \( \mathbb{P}^1 \) with \( (f/g)(\infty) \in \{0, 1, \infty\} \). Another way of saying this is that if \( \deg f = \deg g \) then their leading coefficients are equal, and hence \( \deg(e) < \deg(f) \).

**Proof.** First of all we note that the statement is symmetric in \( e, f, g \), so we may arrange that \( h(g) \leq h(e, f) \) which implies that \( h(e) = h(f) = h(e, f, g) \).

The second statement is less obviously invariant but note that \( \phi \) is a Belyi function is equivalent to \( 1 - \phi \) and \( 1/\phi \) being Belyi also and this preserves \( \phi(\infty) \in \{0, 1, \infty\} \), so rearranging does not change the truth of the second statement either. Let \( \phi = f/g \) so \( \deg(\phi) = \max\{\deg(e), \deg(g)\} = h(e, f, g) \), we will denote this by \( h \) now. Apply Riemann-Hurwitz (surprise-surprise)

\[-2 = -2h + \sum_{x \in \mathbb{P}^1} e_{\phi}(x) - 1.\]

Let

\[ R_y = \sum_{x : f(x) = y} e_{\phi}(x) - 1 \]

be the ramification above \( y \), we will consider \( B_0, B_1, B_{\infty} \). These ramification numbers will simply be \( h - \#(\phi^{-1}(y)) \). Let's begin with \( R_1 \), we have \( f(x)/g(x) = 1 \) so \( e(x) = 0 \) and in fact

\[ R_1 = h(e) - r(e) = h - r(e). \]

For \( R_0 \) we have either \( f(x) = 0 \) or \( g(x) = \infty \). Having \( g(x) = \infty \) means \( x = \infty \) but this cannot really happen as \( h(f) \geq h(g) \). So this is really just

\[ \sum_{x : f(x) = 0} e_{\phi}(x) - 1 = h - r(f). \]

Finally \( \phi(x) = \infty \) only when \( g(x) = 0 \) or \( x = \infty \). If \( h(f) = h(g) \) then \( \phi(\infty) \neq \infty \) and we have simply

\[ R_{\infty} = h - r(g). \]

If \( h(g) < h(f) \) then we also have \( \phi(\infty) = \infty \) so we pick up an extra preimage and we get instead

\[ R_{\infty} = h - (r(g) + 1). \]

Back up in Riemann-Hurwitz this comes down (magically?) to

\[-2 = -2h + h + h + h - r(e) - r(f) - r(g) + R - \delta_{h(f)>h(g)}\]

so

\[ R = h - r(efg) - 2 + \delta_{h(f)>h(g)} \]
but of course $R \geq 0$ so

$$h \geq r(efg) + 1$$

with equality exactly when

$$h = r(efg) + 1 \implies R = 0, h(f) > h(g).$$

$R = 0$ is equivalent to being Belyi. ■

2.10.2 Back to number theory

That was all well and good, but this is a number theory seminar, not a function field analogues of number theory seminar, so let’s take it back to why we are all here, solving Diophantine equations.

Let’s try and find nontrivial integral points on Mordell curves!

$$E_k: y^2 = x^3 + k.$$  

Example 2.10.2

$$1001^2 = 5009^3 - (5009^3 - 1001^2)$$

so I found a large point on

$$y^2 = x^3 - (5009^3 - 1001^2) = x^3 - 125675213728$$

are you not impressed? □

Although this point would look slightly non-trivial if I started with the curve $5009^3$ is roughly $125675213728$ anyway so you should only be impressed if I find points of height somewhat larger than the coefficients. We should probably ask that

$$|x| > |k|$$

by some margin at least.

A nice question is then given $k$ how big can an integer point $(x, y)$ on $E_k$ be? Bounds are known, e.g. Via work of Baker we get

$$\max(|x|, |y|) < e^{10^{10}|k|^{100}}.$$  

Ouch.

If we want to study more realistic bounds we can instead reverse the problem. Can we minimise $x^3 - y^2$ for integer $x, y$, how close can the square of a large integer and the cube of a large integer be? Euler showed that $|x^3 - y^2| = 1$ has only 1 (interesting) solution, for example.

Marshall Hall was interested in this, did some nice computations and conjectured:

Conjecture 2.10.3 Mashall Hall’s conjecture, 1970. If

$$x^3 - y^2 = k$$

for integers $x, y$ then

$$|k| > \frac{\sqrt[3]{|x|}}{5}$$

(or $k = 0...$).

This is false!

Example 2.10.4 Elkies (who else?). If

$$x = 5853886516781223, y = 447884928428402042307918$$
is a point on 
\[ y^2 = x^3 - 164183 \]
then
\[ \frac{\sqrt{|x|}}{k} = 46.6004943471754. \]

This is far larger than the previous best known, but still remains the record as far as I can tell. It seems Hall’s conjecture is unlikely to be true for any fixed constant, but the following of Stark-Trotter is more believable.

**Conjecture 2.10.5 Stark-Trotter/Weak Hall.** For any \( e > 0 \) there is some \( C(e) \) such that for any \( x, y \) integers

\[ |x^3 - y^2| > C(e)x^{\frac{1}{2}-e} \]
for any \( x > C(e) \).

If Hall’s/Stark-Trotter is true we get a huge improvement on Baker

\[ \frac{\sqrt{|x|}}{|k|} < 100 \implies x < 10^4k^2 \]
and hence

\[ y^2 = x^3 + k < 10^{12}k^6 + k \]
giving polynomial bounds on \( x, y \) in terms of \( k \).

How might one find such triple \((x, y, k)\) that is extremal? One approach is to try and come up with a parametrisation of nice triples. We can search for polynomials \( X(t), Y(t), K(t) \) and then plug in various integer values for \( t \) and hope for the best. To give ourselves the best chance of succeeding we want \( K(t) \) to be smaller than \( X(t)^3 \) and \( Y(t)^2 \) for some values of \( t \). This leads us to ask for \( K \) to be of smallest degree possible. So how low can we go?

This is the point where we come full circle right, we are searching for

\[ X(t)^3 - Y(t)^2 = K(t) \]
with degree of \( K \) minimised, so we apply Mason-Stothers to see that, if \( M \) is the degree of the left hand terms we have \( \deg(X) = 2m \) and \( \deg(Y) = 3m \), indeed \( h \) in Mason-Stothers is then \( 6m \) We also have \( r(X^3) = r(X) \leq 2m \) and \( r(X^2) = r(Y) \) \leq 3m \) so together Mason-Stothers gives

\[ 6m < 2m + 3m + r(K) \]
or \( m < r(K) \). So we have lower-bounded the degree of \( K \) in terms of \( \frac{1}{2} \deg(X) \) for example.

We just proved:

**Conjecture 2.10.6 Birch B. J., Chowla S., Hall M., Jr., Schinzel A. On the difference \( x^3 - y^2 \), 1965.** Let \( X, Y \) be two coprime polynomials with \( X^3, Y^2 \) of equal degree (6m) and equal leading coefficient, then

\[ K = X^3 - Y^2 \]
is of degree \( > m \).

(Now the speaker has just given a theorem with an inequality, so in order to appear smart one of you should ask is this bound sharp.)

The bound is sharp, this can mean several things in general, originally it was asked that for infinity many \( m \) there is an example where \( \deg K = m + 1 \).
The first part was proved initially by Davenport (in the same year, and journal). The second part had to wait until ’81 for Stothers to prove it.

Someone else should probably also ask, how is any of this related to Dessins?

To prove sharpness we have to exhibit for each $m$ triple of polynomials $X, Y, K$ of degrees $2m, 3m, m + 1$. Coming up with polynomial families is hard, drawing stupid pictures is easy, can Dessins aid us here?

Let’s back-track, when we proved Mason-Stothers we also said that sharpness was equivalent to $f/g$ being Belyi, so $X(t)/K(t) = (K(t) + Y(t)^2)/K(t) = Y(t)^2/K(t) + 1$ should be a Belyi map of degree $6m$ from $\mathbb{P}^1 \rightarrow \mathbb{P}^1$. What does its ramification look like? We should have all preimages of 0, degree 3, preimages of 1 degree 2, and above infinity $m + 1$ points of degree 1 and the remaining of degree $6m - (m + 1) = 5m - 1$.

How can we draw a Dessin like this? Begin with a tree with all internal vertices degree 3, with $2m$ vertices, this will have $2m - 1$ edges, and as it is trivalent by the handshake lemma

$$3 \# \{\text{internal}\} + \# \{\text{leaves}\} = 4m - 2$$

and

$$\# \{\text{internal}\} + \# \{\text{leaves}\} = 2m$$

giving

$$2 \# \{\text{internal}\} = 2m - 2$$

$$\# \{\text{internal}\} = m - 1$$

$$\# \{\text{leaves}\} = m + 1$$

Add loops to the leaves, you now have a clean Dessin as above. It has $2m - 1 + m + 1 = 3m$ edges. We have a face for every loop of degree 1, and one on the outside of degree $m + 1 + 2(2m - 1) = 5m - 1$ as each internal edge is traversed twice if you walk around the outside. So this works!

**Example 2.10.7** For $m = 1$

$$(x^2 + 2)^3 - (x^3 + 3x)^2 = 3x^2 + 8.$$ 

$m = 2$

$$(x^4 - 4x)^3 - (x^6 - 6x^3 + 6)^2 = 8x^3 - 36.$$ 

\[\square\]

**Example 2.10.8** For $m = 5$

$$X(t) = \frac{1}{9}(t^{10} + 6t^7 + 15t^4 + 12t)$$

$$Y(t) = \frac{1}{54}(2t^{15} + 18t^{12} + 72t^9 + 144t^6 + 135t^3 + 27)$$

$$K(t) = -\frac{1}{108}(3t^6 + 14t^3 + 27)$$

and we can let $t = -3$ to get $X(-3) = 5234, Y(-3) = -378661$ and $K(-3) = -17$, so we have a point

$$(5234, 378661) \in E_{17}: y^2 = x^3 + 17$$

letting $t = \pm 9$ we get

$$|384242766^3 - 7531969451458^2| = 14668$$
both of which have
\[ \frac{\sqrt{|x|}}{k} \approx 1.33, \]
these get lower as we increase \( t \) though.

We should expect this decrease from this method as if \( \deg X = 2m \) and \( \deg K = m + 1 \) then \( \sqrt{X(t)}/K(t) \) grows like \( t^m/t^{m+1} = t^{-1} \).

Can we do the same for \( abc \)?

Take the Dessin with a deg 1 vertex at infinity, degree 3 at 0 with an edge surrounding 1, we get a Belyi function

\[ f(x) = \frac{64x^3}{(x+9)^3(x+1)}, \quad f(x) - 1 = -\frac{(x^2 - 18x - 27)^2}{(x+9)^3(x+1)} \]

plugging in \( x = a/b \) and cross multiplying gives

\[ 64a^3b + (a^2 - 18ab - 27b^2)^2 = (a + 9b)^3(a + b) \]

which could of course be verified independently, but how would you find this identity without Dessins? Now for \( a = -32, b = 23 \) we get

\[ -2^{21} \cdot 23 + 11^2 = -1 \cdot 3^2 \cdot 5^6 \cdot 7^3 \]

or

\[ 11^2 + 3^2 \cdot 5^6 \cdot 7^3 = 2^{21} \cdot 23 \]

This is the second highest quality abc triple known with quality

\[ \frac{\log c}{\log R} = 1.62599 \]

(the current winner has quality 1.6299).

2.11 Three Short Stories about Belyi’s theorem (Ricky)

Theorem 2.11.1 $X/\mathbb{C}$ a curve. Then $X$ is defined over $\overline{\mathbb{Q}}$ iff there exists a Belyi map $\phi: X \to \mathbb{P}^1$

such that $B(\phi) \subseteq \{0, 1, \infty\}$.

Main reference: Unifying Themes Suggested by Belyi’s Theorem - Wushi Goldring
2.11.1 The case of the Rising Degree

Definition 2.11.2 The Belyi degree of $X/\overline{\mathbb{Q}}$ (a curve) is the minimal degree of $\phi: X \to \mathbb{P}^1$ a Belyi map.

Question, how does the Belyi degree of $X/\overline{\mathbb{Q}}$ relate to the arithmetic of $X$?

Definition 2.11.3 The field of moduli of $X/\overline{\mathbb{Q}}$ is the intersection over all fields $K \subseteq \overline{\mathbb{Q}}$ over which $X$ is defined. Similarly for a morphism $\phi: X \to Y$.

Remark 2.11.4 This is not the same as the field of definition always.

Given $X/\overline{\mathbb{Q}}$ with field of moduli $K$ we say $X$ has good (resp. semistable) reduction at $p$ if there exists a model for $X$ over $O_K$ s.t. the special fibre is smooth (resp. semistable) reduction.

For $p \in \mathbb{Z}$ we say $X$ has good/semistable reduction at $p$ if it dies for all $\mathfrak{p}|p$.

Theorem 2.11.5 Zapponi. If $X/\overline{\mathbb{Q}}$ then the Belyi degree of $X$ is at least the largest prime $p \in \mathbb{Z}$ such that $X$ has bad semistable reduction at $p$.

Remark 2.11.6
1. The lower bound is not “sharp” because there exist $E/K$ with good reduction everywhere, but no degree 1 maps $\phi: E \to \mathbb{P}^1$.

2. If $E: y^2 = x^3 + x^2 + p$

then $E$ has bad semistable reduction at $p$ so the Belyi degree of $E$ is $\geq p$.

Theorem 2.11.7 Beckmann. Let $\phi: X \to \mathbb{P}^1$ be a Belyi map with field of moduli $M$. Let $G$ be the Galois group of the Galois closure of $\phi$. Then for all $p$ such that $p \nmid |G|$, $\tilde{\phi}: \tilde{X} \to \mathbb{P}^1$ has good reduction at $p$ and $p$ is unramified in $M$.

Proof. Of Zapponi.

Let $\phi: X \to \mathbb{P}^1$ be a Belyi map of degree $n$. Let $K$ be the field of moduli of $X$, $M$ the field of moduli of $\phi$ then $M/K$ is a finite extension. Take $G$ as above and let $\mathfrak{p} \subseteq O_K$ be a place of bad semistable reduction for $X$. Then $\phi|_{\mathfrak{p}}$ for $\phi \subseteq O_M$ is a place of bad semistable reduction for $\phi$. By Theorem 2.11.7 $p \nmid |G|$ for $p \in \mathbb{Z}$ below but $G \hookrightarrow S_n$ which implies $p|n!$ so $p \leq n$. ■

2.11.2 Finitists Dream

Recall that if $k$ is a perfect field of characteristic $p$ then

$\phi: C_1 \to C_2$

is said to be tamely ramified at $P \in C_1$ if $p \nmid e_\phi(P)$ (wildly ramified if $p|e_\phi(P)$).

Theorem 2.11.8 Wild $p$-Belyi. For $C$ a curve over $k$ perfect of characteristic $p$, there exists a “wild Belyi map”

$\phi: C \to \mathbb{P}^1$

such that $B(\phi) = \{\infty\}$. I.e. every curve over $k$ is birational to an étale cover of $\mathbb{A}^1$.

Example 2.11.9

$\mathbb{G}_m \to \mathbb{A}^1$

$x \mapsto x^p + \frac{1}{x}$

but the tame étale fundamental group of $\mathbb{A}^1$ is 0. □
Theorem 2.11.10 Tame $p$-Belyi (Saidi). Let $p > 2$. For $C/\overline{\mathbb{F}}_p$ there exists $\phi: C \to \mathbb{P}^1$ tamely ramified everywhere (i.e. possibly unramified) with

$$B(\phi) \subseteq \{0, 1, \infty\}.$$ 

Lemma 2.11.11 Fulton. Let $p > 2$ then for $C/k$ ($k$ algebraically closed of characteristic $p$) there exists $\psi: C \to \mathbb{P}^1$ such that

$$e_\psi(P) \leq 2.$$ 

Proof. Of Tame $p$-Belyi

Take $\psi: C \to \mathbb{P}^1$ as in the lemma then

$$B(\psi) \subseteq \mathbb{P}^1(\mathbb{F}_p^m)$$

for some $m$. Define

$$f: \mathbb{P}^1 \to \mathbb{P}^1$$

by

$$x \mapsto x^{p^m-1}.$$ 

Take $\phi = f \circ \psi$. So $\pi$ is tamely ramified everywhere and $B(\phi) \subseteq \{0, 1, \infty\}$. ■

Analogue of Fulton’s lemma is that there exists $\tau: C \to \mathbb{P}^1$ for $\text{char}(k) \neq 3$ such that $e_\tau(P) = 1$ or $3$.

2.11.3 In the Stacks

Observation 2.11.12 $\mathbb{P}^1 \setminus \{0, 1, \infty\}$ is the moduli space of genus 0 curves with four (ordered) marked points.

$$(\mathbb{P}^1, \alpha_1, \alpha_2, \alpha_3, \alpha_4) \mapsto \text{im}(\alpha_4) \text{ when } \alpha_1 \mapsto 0, \alpha_2 \mapsto 1, \alpha_3 \mapsto \infty.$$ 

Definition 2.11.13 Let $M_{g,[n]}$ be the moduli space of genus $g$ curves with $n$ (ordered) marked points (then $M_{g,[n]}$ is the same for unordered points). If $n$ is large enough relative to $g$ then $M_{g,n}$ will be a scheme (but the unordered version will not).

Example 2.11.14

$$M_{0,4} \cong \mathbb{P}^1 \setminus \{0, 1, \infty\}$$

□

Question 2.11.15 Braungardt. Is every $X/\overline{\mathbb{Q}}$ (smooth projective variety) birational to a finite étale cover of some $M_{g,[n]}$? □

Note 2.11.16 There exists an étale map

$$M_{g,n} \to M_{g,[n]}$$

by forgetting the ordering of the points.

So the dimension 1 case of the conjecture is Belyi’s theorem, by

$$X \setminus \phi^{-1}(B(\phi)) \to \mathbb{P}^1 \setminus \{0, 1, \infty\} \cong M_{0,4} \to M_{0,[4]}.$$ 

In dimension 2 we have $M_{1,[2]}$ and $M_{0,[5]}$, the only 2-d spaces of interest. We also have an étale map

$$M_{1,[2]} \to M_{0,[5]}$$
as follows: 
\[ \eta = (E; \{q_1, q_2\}) \in M_{1,2} \]

with 
\[ \alpha(\eta) = (P^1; \{r_1, r_2, r_3, r_4, r_5\}) \]

where the \( r_i \) come from constructing a projection \( \phi \) from \( E \) to \( P^1 \) situated perpendicularly to the line joining \( q_1, q_2 \). This then has 4 ramification points 
\[ B(\phi) = \{r_1, r_2, r_3, r_4\} \]

and \( r_5 = \phi(q_1) = \phi(q_2) \). So Braungardt for surfaces \( (X/\overline{Q}) \)? Does there exist \( \phi: X \to M_{0,5} \) which is étale?

**Theorem 2.11.17 Braungardt.** For \( X/\overline{Q} \) an abelian surface \( X \) is birational to an étale cover of \( M_{0,5} \).

**Proof.** Sketch.

For an abelian surface over \( \overline{Q} \) there exists another isogenous to it which is principally polarized. Such surfaces come in two flavours 
\[ E_1 \times E_2 \]

or \( J(C) \) for \( C \) of genus 2.

Case 1:

Let \( \phi_i: E_i \to P^1 \setminus \{0,1,\infty\} \) be Belyi maps. Then we have \( \alpha: A \xrightarrow{\phi_1,\phi_2} P^1 \times P^1 \). Then \( \alpha \) restricts to a finite unramified cover 
\[ \alpha^{-1}(S) \xrightarrow{\alpha} S \]

where 
\[ S = (P^1 \setminus \{0,1,\infty\} \times P^1 \setminus \{0,1,\infty\}) \setminus \Delta. \]

Note that \( S \approx M_{0,5} \) by 
\[ (a, b) \mapsto (P^1; \{0,1,\infty,a,b\}). \]

So \( A \) is birational to \( \alpha^{-1}(S) \) which is an étale cover of \( M_{0,5} \).

Case 2

If \( A = J(C) \) then use \( \phi: C \to P^1 \) and a relation between \( A \) and \( \text{Sym}^2(C) \). ■

**2.12 Dessins in Physics (Jim)**

**Physics.** Let \( M \) be a manifold with a metric \( g \). We call the pair \( (M,g) \) a “spacetime manifold”. Let \( E \) be a “space of fields”, either \( C^\infty(M) \), sections of some \( E \to M \), connections, or similar.

\[ S(\phi) = \int_M L(\phi) \]

for \( \phi \in E \) and \( L \) the Lagrangian. “Physically realisable states” are then fields \( \phi \) that minimise \( S(\phi) \). \( W \) is a superpotential, this is a term in \( L \) that satisfies some special symmetries. E.g. we could also have 
\[ S(\phi_1, \phi_2) = \int_M L(\phi_1, \phi_2) \]

the \( W \) might satisfy \( W(\phi_1, \phi_2) = W(\phi_2, \phi_1) \).
Definition 2.12.1 Gauge transformations. Let $G \curvearrowright E \xrightarrow{p} M$ be an action s.t. each fibre $E_x = p^{-1}(x)$ is a representation of $G$. A gauge is a section $s(x)$ of $E \to M$. A gauge transformation is a map $g : M \to G$ s.t.

$$g(x)s(x)$$

is another section, call $G$ the gauge group. The important gauge transformations are the ones that fix the set of physically realisable states (i.e. fixes the subset of $E$ that minimise $S$).

Quivers and dessins. Let’s now study the relationship between quivers and dessins.

Example 2.12.2 $\mathcal{N} = 4$ SYM (supersymmetric Yang-Mills) (Gauge symmetries given by some product of $\text{SU}(N)$).

A quiver is a directed graph, possibly with self-loops. Here we think of the nodes as corresponding to factors of the gauge group. And the arrows as fields, so in a bouquet with 3 petals we have three fields, and only $G = \text{SU}(N)$.

There is also the notion of a periodic quiver (a tiling of the plane). We can take the triangular lattice and consider its dual, this is a hexagonal tiling with a bicolouring corresponding to the fact we had upwards pointing and downwards pointing triangles. This is a Dimer model.

Relating the Dimer model back to physics: We have hexagonal faces in correspondence with factors of the Gauge group, and edges fields, with vertices terms in $W$.

So one distinct face gives one factor in the gauge group so $G = \text{SU}(N)$. 3 distinct edges give 3 fields $X_1, X_2, X_3$. To recover $W$ consider the permutation arising from reading the edges around the vertices counterclockwise. A black vertex $(1,2,3)$ gives $\sigma_B$ corresponding to a positive term in $W$. A white vertex $(1,2,3)$ gives $\sigma_W$ corresponding to a negative term in $W$. Then $\sigma_{\infty} = (\sigma_B \sigma_W)^{-1} = (123)$ $\sigma_i$ gives a term for each cycle. Each cycle in $\sigma_B$ gives a product of fields indexed by the cycle, e.g. in this example $\sigma_B$ gives $X_1 X_2 X_3$. Each cycle in $\sigma_W^{-1}$ gives a product of fields indexed by the cycle, e.g. in this example $\sigma_W$ gives $X_1 X_3 X_2$. Then

$$W = \text{Tr}((\text{sim of } \sigma_B \text{ terms}) - (\text{sim of } \sigma_W \text{ terms})) = \text{Tr}(X_1 X_2 X_3 - X_1 X_3 X_2).$$

Aut($\{\sigma_B, \sigma_W, \sigma_{\infty}\}$) = \{ $\gamma \in S_3 : \gamma \sigma_i \gamma^{-1} = \sigma_i$ \} = \{1, (123), (132)\} = $Z/3Z$.

The fundamental domain of the Dimer gives a dessin on the torus with two vertices of degree 3. This corresponds to the Belyi pair $(\Sigma, \beta)$ where

$$\Sigma : y^2 = x^3 + 1$$

$$\beta : \Sigma \to \mathbb{P}^1$$

$$(x, y) \mapsto \frac{y + 1}{2}.$$

Aut($\Sigma, \beta$) = Aut($\{\sigma_B, \sigma_W, \sigma_{\infty}\}$)

Aut($\Sigma, \beta$) is generated by

$$(x, y) \mapsto (w^3 x, y)$$

where $w^3 = 1$. 

Example 2.12.3 Take the quiver with two vertices and two edges in each direction connecting them. This has 4 fields and two factors of $G$ (i.e. $G = \text{SU}(N) \times \text{SU}(N)$). The dimer is a square lattice alternately coloured, with $\sigma_B = (1234), \sigma_\infty = (13)(24)$.

$$W = \text{Tr}(X_1X_2X_3X_4 - X_1X_4X_3X_2).$$

In this case the Belyi pair is

$$\Sigma: y^2 = x(x - 1)(x - \frac{1}{2})$$

$$\beta = \frac{x^2}{2x - 1}.$$

$$\text{Aut} \{\sigma_B, \sigma_W, \sigma_\infty\} = \langle (1234) \rangle \approx \mathbb{Z}/4\mathbb{Z}$$

$$\phi_\pm: (x, y) \mapsto \left(\frac{x}{2x - 1}, \frac{\pm i}{(2x - 1)^2}\right)$$

$$\phi_+^2 = \phi_2^2: (x, y) \mapsto (x, -y)$$

$$\phi_+^3 = \phi_+^{-1} = \phi_-$$. 

$$\phi_+^4 = 1$$

so

$$\text{Aut}(\Sigma, \beta) \approx \mathbb{Z}/4\mathbb{Z}$$

$$\beta^{-1}(0) = \{(0, 0)\}$$

$$\beta^{-1}(1) = \{(1, 0)\}$$

$$\beta^{-1}(\infty) = \{(\frac{1}{2}, 0), (\infty, \infty)\}$$

on the Dimer we have the square lattice so taking a fundamental domain containing of the vertices we see the torus as a topology. \(\square\)

Example 2.12.4 Final example. Let's jump straight to the Dimer the hexagonal lattice with fundamental domain containing 6 vertices. We have 9 fields and three factors in the gauge group $G = \text{SU}(N)^2$.

$$\sigma_B = (147)(258)(369)$$

$$\sigma_W = (123)(456)(789)$$

$$\sigma_\infty = (195)(276)(384)$$

so

$$W = \text{Tr} \sum_{i,j,k} X_{12}^i X_{23}^j X_{31}^k \epsilon_{ijk}$$

where

$$\epsilon_{ijk} = \begin{cases} 
\text{sgn}(ijk) & \text{if } i, j, k \text{ distinct} \\
0 & \text{otw} 
\end{cases}$$

$X_{12}^i$ acts on the $i$th field by $N, \tilde{N}, 1$ where $N$ is the canonical representation, $\tilde{N}$ the anticanonical and 1 is trivial.

$$\text{Aut} \{\sigma_B, \sigma_W, \sigma_\infty\} = \mathbb{Z}/3\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$$

now the Belyi pair

$$\Sigma = \text{projective closure of } F = \{(x, y) : x^3 + y^3 = 1\}$$
\[ \beta(x, y) = x^3 \]
\[ \gamma_1(x, y) = (w_1 x, y) \]
\[ \gamma_2(x, y) = (x, w_2 y) \]
\[ w_i^3 = 1. \]
Chapter 3

Supersingular isogeny graphs and Quaternion Algebras

These are notes for BUNTES Fall 2018, the topic is Supersingular isogeny graphs and Quaternion Algebras.

Outline:
1. Background, isogeny graphs, applications.
2. Supersingular isogeny graph cryptography (candidate for post-quantum cryptography).
3. Introduction to Quaternion algebras.
4. The Deuring correspondence:
   \[
   \left\{ \text{maximal orders } O \subseteq B_{p,\infty} \right\} / \sim \leftrightarrow \left\{ \text{j s.s. } \in \mathbb{F}_{p^2} \right\} / \text{Gal}(\mathbb{F}_{p^2}/\mathbb{F}_p).
   \]

References: [82, 89, 88]

3.1 Isogeny graphs: background and motivation (Maria Ines)

3.1.1 Background
Let \( k = \mathbb{F}_q, \text{char}(k) = p \neq 2, 3. \)

Definition 3.1.1 Elliptic curves. An elliptic curve \( E/k \) is a smooth projective curve of genus 1 together with a point \( \infty \in E(k). \)

We can always write such a curve using a Weierstrass equation

\[
E: \quad y^2 = x^3 + ax + b, \quad a, b \in k
\]

\( E \) is really the projective closure of this affine equation.

Definition 3.1.2 \( j \)-invariants. The \( j \)-invariant of an elliptic curve \( E \) is

\[
j(E) = j(a, b) = 1728 \frac{4a^3}{4a^3 + 27b^2}
\]

doesn’t depend on the choice of Weierstrass equation.
Fact 3.1.3
1. \( E, E' \) are isomorphic over \( \overline{k} \) \iff \( j(E) = j(E') \).
2. There is a 1-1 correspondence

\[ k \leftrightarrow \overline{k}-\text{isomorphism classes of EC's } /k. \]

Definition 3.1.4 Isogenies. Let \( E, E'/k \) be elliptic curves. An isogeny, \( \phi : E \to E' \) is a non-constant morphism of pointed curves. The degree \( \text{deg } \phi \) is the degree as a morphism. \( E, E' \) are said to be \( n \)-isogenous if there exists \( \phi : E \to E' \) of degree \( n \). \( j, j' \in k \) are \( n \)-isogenous if the corresponding elliptic curves are.

Fact 3.1.5
1. If \( p \nmid n \) then \( \text{deg } \phi \) is separable.
2. Every finite subgroup of \( E(\overline{k}) \) is the kernel of a separable isogeny from \( E \), unique up to isomorphism.
3. Every \( n \)-isogeny \( \phi : E \to E' \) has a dual isogeny \( \hat{\phi} : E' \to E \) such that

\[ \phi \circ \hat{\phi} = \hat{\phi} \circ \phi = [n], \]

the multiplication-by-\( n \) map.
4. The \( n \)-torsion subgroup

\[ E[n] = \left\{ P \in E(\overline{k}) : nP = \infty \right\} \]

is isomorphic to \( (\mathbb{Z}/n)^2 \) if \( p \nmid n \).

Lemma 3.1.6 Let \( E/k \) be an elliptic curve with \( j(E) \notin \{0, 1728\} \) and let \( l \neq p \) be prime, up to isomorphism the number of \( l \)-isogenies from \( E \) defined over \( k \) is 0,1,2 or \( l + 1 \).

Proof. In Maria’s notes.

The modular equation. Let \( j(\tau) \) be the modular \( j \)-function. For each prime \( l \) the minimal polynomial \( \phi_l \) of \( j(l\tau) \) over \( \mathbb{C}(j(\tau)) \) is the modular polynomial

\[ \phi_l \in \mathbb{Z}[j(\tau)][y] \approx \mathbb{Z}[x, y]. \]

Fact 3.1.7
1. \( \phi_l \) is symmetric in \( x, y \) and has a degree \( l + 1 \) in both variables.
2. The modular equation

\[ \phi_l(x, y) = 0 \]

is a canonical model for

\[ Y_0(l) = \Gamma_0(l) \backslash \mathcal{H} \]

it parameterises pairs of elliptic curves related by an \( l \)-isogeny. This moduli interpretation is still valid when we use any field \( F \) with \( \text{char}(F) \neq l \).
3. Let \( m_l(j, j') = \text{ord}_{t=j'} \phi_l(j, t) \), whenever \( j, j' \neq 0, 1728 \),

\[ m_l(j, j') = m_l(j', j). \]
The endomorphism ring.  Definition 3.1.8 Endomorphisms of elliptic curves.  
An endomorphism of an elliptic curve $E$ is either the zero map or an isogeny from $E$ to itself. They form a ring $\text{End}(E)$. 

For $n \in \mathbb{Z}$ we have $[n] \in \text{End}(E)$ so $\mathbb{Z} \subseteq \text{End}(E)$ over a finite field $k$, $\text{End}(E)$ is always larger than $\mathbb{Z}$. It is either an order in an imaginary quadratic field, in which case we say $E$ is ordinary. Or an order in a quaternion algebra, in which case we say $E$ is supersingular. We say $E$ has complex multiplication by $O$.

Proposition 3.1.9 Let $E/k = F_{p^n}$ be an elliptic curve, TFAE 
1. $E$ is supersingular.
2. $E[p]$ is trivial.
3. The map $[p]: E \to E$ is purely inseparable and $j(E) \in F_{p^2}$.

Note 3.1.10 If $E, E'$ are isogenous elliptic curves then $\text{End}(E) \otimes \mathbb{Z} \cong \text{End}(E') \otimes \mathbb{Z}$. So supersingularity is preserved by isogenies.

Isogeny graphs of elliptic curves.  Let $k = F_q$ with $\text{char}(k) = p$ and $l \neq p$ be prime.

Definition 3.1.11 Isogeny graphs.  The $l$-isogeny graph $G_l(k)$ is the directed graph with vertex set $k$ and edges $(j, j')$ present with multiplicity $m_j(l, l') = \text{ord}_{t=j} \phi_l(j, t)$ vertices are $\overline{k}$ isomorphism classes of elliptic curves $/k$, edges are isomorphism classes of $l$-isogenies defined over $k$.

Since $m_j(j, j') = m(j', j)$ whenever $j, j' \neq 0, 1728$ the subgraph of $G_l(k)$ supported on $k \setminus \{0, 1728\}$ can be thought of as undirected. By the last note $G_l(k)$ consists of ordinary and supersingular components.

Supersingular isogeny graphs.  Since every supersingular $j$-invariant lives in $F_{p^2}$ if $E$ is supersingular all roots of $\phi_l(j(E), y)$ live in $F_{p^2}$. Every vertex in a supersingular component has out-degree $l + 1$.

Moreover by a result of Kohel $G_l(F_{p^2})$ has only one supersingular component.

By the above if $p \equiv 1 \pmod{12}$ then the supersingular component of $G_l(F_{p^2})$ is an undirected $(l + 1)$-regular graph with around $p/12$ vertices.

Theorem 3.1.12 Pizer.  The supersingular component of $G_l(F_{p^2})$ is a Ramanujan graph.

Definition 3.1.13 Ramanujan graphs.  A connected $d$-regular graph is a Ramanujan graph if $\lambda_2 \leq \sqrt{d - 1}$ where $\lambda_2$ is the second largest eigenvalue of its adjacent matrix. (The largest one is always $d$, by $d$-regularity.)

Ordinary isogeny graphs.  Let $E/F_q$ be an ordinary elliptic curve, then $\text{End}(E) \cong \mathcal{O}$ is an order in an imaginary quadratic field $K$ with $\mathbb{Z}[\pi] \subseteq \mathcal{O} \subseteq \mathcal{O}_K$ where $\pi$ is Frobenius and $K = \mathbb{Q}(\sqrt{(\text{Tr } \pi)^2 - 4q})$ by Tate, isogenous elliptic curves have the same $\text{Tr } \pi$. 

We can separate the vertices in the component $V$ of $G\ell(k)$ containing $j(E)$ into levels $V_0, \ldots, V_d$ so that $j(E') \in V_i$ if $i = \nu_j([O_K : O'])$. We’ll see that $\bigcup_{i=0}^{d} V_i$ is connected.

Let $\phi: E \to E'$ be an $l$-isogeny between two elliptic curves with CM by $O = \mathbb{Z} + \tau\mathbb{Z}, O' = \mathbb{Z} + \tau'\mathbb{Z}$. Then $\phi\tau'\phi \in \text{End}(E) \Rightarrow l\tau \in O$. Similarly $l\tau' \in O'$. There are 3 cases

1. $O = O'$ ($\phi$ is horizontal).
2. $[O : O'] = l$ ($\phi$ is descending).
3. $[O' : O] = l$ ($\phi$ is ascending).

In the last two cases we say $\phi$ is critical.

**Horizontal isogenies.** $E/k$ with CM by $O \subseteq K$ imaginary quadratic. Let $a$ be an invertible ideal.

$$E[a] = \{P \in E(\overline{k}) : \alpha(P) = 0 \forall \alpha \in a\}$$

this is a finite group so it is the kernel of a separable isogeny $\phi_a$. If $p \nmid N(a)$ then $\deg(\phi_a) = N(a)$ with a invertible implying $\phi_a$ is horizontal.

Each horizontal $l$-isogeny $\phi$ arises from some invertible ideal $a$ of norm $l$. If $l||O_K : O|$ no such ideals exist, otherwise the number of invertible ideals of norm $l$ is

$$1 + \left(\frac{\text{disc}(K)}{l}\right) = \begin{cases} 0 & \text{if } l \text{ inert} \\ 1 & \text{if } l \text{ ramified} \\ 2 & \text{if } l \text{ splits} \end{cases}$$

**Vertical isogenies.** Let $O$ be an order in an imaginary quadratic field $K$ of discriminant $D < -4$ and let $O' = \mathbb{Z} + lO$.

**Lemma 3.1.14** Let $E'/k$ be an elliptic curve with CM by $O'$ then there is a unique ascending $l$-isogeny $E' \to E$ with $E/k$ an elliptic curve with CM by $O$.

**Definition 3.1.15** An $l$-volcano $V$ is a connected undirected graph whose vertices are partitioned into levels $V_0, \ldots, V_d$.

1. The subgraph $V_0$ is regular of degree $\leq 2$.
2. For each $i > 0$ each vertex in $V_i$ has exactly one neighbour in level $V_{i-1}$, and this accounts for all edges outside of $V_0$.
3. For $i < d$ each vertex has degree $l + 1$.

The number $d$ is the depth.
Figure 3.1.16 A 3-volcano

The Sage code used to make this picture was:

```python
N = 3  # number of flows
p = 3
D = 2
G = graphs.BalancedTree(p,d)  # a (p+1)-regular tree of depth d
G.delete_edge(G.edges()[0])
F = G.subgraph(G.connected_component_containing_vertex(0))  # A single 'flow'
H = N*F
H.add_cycle([len(F.vertices())*i for i in range(N)])
show(H)
#latex(H) # for the code
```

**Theorem 3.1.17 Kohel.** Let $V$ be an ordinary component of $G_l(F_q)$ that doesn’t contain 0 or 1728 then $V$ is an $l$-volcano s.t.

1. All vertices in $V_i$ have the same endomorphism ring $O_i$.

2. The subgraph on $V_0$ has degree

$$1 + \left(\frac{\text{disc}(K)}{l}\right)$$

where $K = \text{Frac}(O_0)$
3. If \( \left( \frac{\text{disc}(K)}{l} \right) \geq 0 \)

then \( \#V_0 \) is the order \(|I|\) in \( \text{Cl}(O_0) \) else \( \#V_0 = 1. \)

4. The depth of \( V \) is \( d = v_l([O_K : \mathbb{Z}]) \) where \( \pi \) is the Frobenius morphism on any \( E \) with \( j(E) \in V. \)

5. \( l \nmid [O_K : O_0] \), \( [O_i : O_i + 1] = 1 \) for \( 0 \leq i < d. \)

Application: Identifying supersingular elliptic curves. Algorithm 3.1.18 Sutherland.

Input: Elliptic curve \( E/k \), char \( k = p \).

Output: Ordinary or supersingular.

1. If \( j(E) \notin \mathbb{F}_{p^2} \) then ordinary.
2. If \( p = 2,3 \) return supersingular if \( j(E) = 0 \) or ordinary otherwise.
3. Find 3 roots of \( \phi_2(j(E), 4) \) over \( \mathbb{F}_{p^2} \) if not possible return ordinary.
4. Walk 3 paths in parallel for up to \( \lceil \log_2 p \rceil + 1 \) steps. If any of these paths get to \( V_d \), return ordinary.
5. Otherwise supersingular.

3.2 Supersingular isogeny graph cryptography (Asra)

Supersingular isogeny graph crypto is a candidate for post-quantum crypto, not based on factoring etc.

Recall last time we defined Ramanujan graphs, graphs with very good connectivity properties, a type of expander.

**Proposition 3.2.1** If \( G \) is a Ramanujan graph, \( x \in V, S \subseteq V \). For a sufficiently large path beginning at \( x \), the probability that the path ends in \( S \) is at least \( |S|/2|V| \).

Upshot: supersingular isogeny graphs are \((l + 1)\)-regular, undirected, Ramanujan, connected (technically, Ramanujan means connected already, but its worth emphasising).

Some of our algorithms are only dependent on having a graph with this property, not so much the interpretation in terms of isogenies.

Supersingular isogeny graphs first appeared in crypto as potential hash functions.

3.2.1 Hash functions

(2010) (Charles, Goren, Lauter) proposed a cryptographically secure hash function based on the hardness of computing paths in a supersingular isogeny graphs.

**Definition 3.2.2** Hash functions. A hash function is a deterministic function \( h: \{0,1\}^* \rightarrow \{0,1\}^n. \)

**Definition 3.2.3** Collision resistance. A hash function \( h \) is collision resistant if its hard to find \( x_1, x_2 \) with \( x_1 \neq x_2 \) s.t. \( h(x_1) = h(x_2). \)

**Definition 3.2.4** Preimage resistance. A hash function \( h \) is preimage resistant if given \( y \in \{0,1\}^n \) its hard to find \( x \) s.t. \( h(x) = y. \)
CHAPTER 3. SUPERSINGULAR ISOGENY GRAPHS AND QUATERNION ALGEBRAS

Cool example, private set intersection, say two groups, Starbucks and BU want to find a list of common customers (students who bought something at Starbucks) but don’t want to reveal anything to each other about the students or customers not in the intersection. Compute hashes of the names of customers and share the hashes, can compute the size of, and the intersection itself.

3.2.2 Supersingular isogeny hash functions

Parameters. \( G_l(F_{p^2}), \ p \equiv 1 \pmod{12}, l \) to be small, fix an ordering on the edges, fix an initial vertex \( j_0 \) and an incoming edge.

Protocol. \( m \in \{0, 1\}^* \) write this as an \( l \)-bit string, \( m \in \{0, 1, \ldots, l-1\}^* \), walk the graph based on \( m \) without backtracking.

Map the final \( j \) invariant to \( \{0, 1\} \approx \log p \).

Properties. Difficult means exponential in the size of the input normally.

Proposition 3.2.5

1. Preimage resistant iff when given \( j \) it is difficult to compute a positive integer \( e \) and an isogeny \( \phi : E_{j_0} \to E_j \) with degree \( l^e \).

2. Collision resistant iff when given \( j \) it is difficult to compute \( e \) and \( \phi : E_{j_0} \to E_{j_0} \) with degree \( l^e \).

3.2.3 Diffie-Hellman Key Exchange (1976)

Choose \( p, Z/p, g \) then Alice computes \( g^a \) send to Bob, he computes \( g^b \) and sends it back, they both compute \( g^{ab} \), which is their shared secret.

The security is based on the hardness of computing \( g^{ab} \) given \( g^a, g^b \).

3.2.4 Supersingular isogeny Diffie-Hellman (SIDH)

Parameters. Supersingular elliptic curve of smooth order: fix \( p \) to be big enough \( p = l_A^{e_A} l_B^{e_B} f + 1 \). \( l_A, l_B \) small primes, \( f \) is a number chosen such that \( p \) is big. Construct a supersingular elliptic curve \( E \) such that \( #E(F_{p^2}) = (l_A^{e_A} l_B^{e_B} f)^2 \), using Broker’s algorithm.

Construct bases \( (P_A, Q_A) \) for \( E[l_A^{e_A}] \), \( (P_B, Q_B) \) for \( E[l_B^{e_B}] \).

Protocol. Alice takes \( m_A, n_A \in Z/l_A^{e_A} \)

Bob takes \( m_B, n_B \in Z/l_B^{e_B} \)

Alice finds \( R_A = m_A P_A + n_A Q_A \)

Bob finds \( R_B = m_B P_B + n_B Q_B \)

Alice finds \( \phi_A : E \to E/(R_A) = E_A \)

Bob finds \( \phi_B : E \to E/(R_B) = E_B \)

They send each other \( E_i, \phi_i(P_i), \phi_i(Q_i) \).

Both compute \( \phi_A^*: E_B \to E_B/(m_A \phi_B(P_A) + n_A \phi_B(Q_A)) \) or analogous.

Shared secret is \( j(E_{AB}) \).

Hardness.

1. (Decisional supersingular isogeny problem) Given \( E, (P_A, Q_A) \) a basis for \( l_A^{e_A} \) torsion, let \( E_A \) be another curve, is \( E_A l_A^{e_A} \) isogenous to \( E \)?
2. (Computational supersingular isogeny problem) Let \( \phi_A : E \to E_A \) be an isogeny with a kernel of the form \( \langle m_A P_A + n_A Q_A \rangle \). Given \( E_A \) and \( \phi_A(P_B) \), find \( R_A = p^{1/4} \) classical, \( p^{1/6} \) quantum.

3. Given \( E_A, E_B, \phi_A(P_B), \phi_A(Q_B), \phi_B(P_A), \phi_B(Q_A) \) find \( j \)-invariant of \( E_{AB} \).

### 3.2.5 Supersingular isogeny public key

Classically DH key-exchange \( \sim \) ElGamal encryption.

1. Key generation.
   Alice: secret \( \phi_A : E \to E_A \), public \( E_A \) and \( \phi_A(P_B), \phi_A(Q_B) \).

2. Encryption.
   Bob: choose \( \phi_B : E \to E_B \), compute \( j(E_{AB}) \).
   Send Alice \( c = (E_B, \phi_B(P_A), \phi_B(Q_A), m \oplus j(E_{AB})) \)

3. Decryption.
   Alice use \( (E_B, \phi_B(P_A), \phi_B(Q_A)) \) to compute \( j(E_{AB}) \). Computes \( (m \oplus j(E_{AB})) \oplus j(E_{AB}) = m \).

\( E(F_p^2), p = l_A^{e_A} l_B^{e_B} f \pm 1 \), for 128-bit security use a 512-bit key.

### 3.2.6 Algorithmic aspects

1. (Choosing \( f \)) Prime number theorem for arithmetic progressions gives you a bound on the density of primes of the form \( l_A^{e_A} l_B^{e_B} f \pm 1 \)

2. Choosing a s.s. e.c. with the right group order, Broker’s algorithm.

3. Finding a basis for \( E[l_A^{e_A}] \).
   (a) Find a random point in \( E(F_p^2) \) say \( P \).
   (b) Check the order of \( (l_B^{e_B} f)^2 \cdot P \). If its \( l_A^{e_A} \) set \( P_A = P \). Otherwise repeat from 1.
   (c) Do the same with \( Q_A = Q \).
   (d) Check independence by seeing if \( e(P_A, Q_A) \) has the right order, so that it is in \( E[l_A^{e_A}] \) torsion.

4. Computing the kernels generated by \( R_A = m_A P_A + n_A Q_A, m_A, n_A \in \mathbb{Z}/l_A^{e_A} \mathbb{Z} \). Analogue of double and add. Set \( R_A = P_A + [m_A^{-1} n_A] Q_A \). Use differential addition (when you compute \( A + B \) with side info \( A - B \)) and a Montgomery ladder

5. (Computing smooth degree isogenies) Decompose the \( l_A^{e_A} \) isogeny into \( e_A \) different \( l_A \)-isogenies, \( \phi_i : E_i \to E_{i+1} \) the kernel of \( \phi_i \) is \( \langle l_A^{e_i - i} R_A \rangle \). Vélu’s formula runs in \( O(l) \) for \( l \)-isogeny.

### 3.3 Quaternion Algebras (Alex)

Q: Why study quaternion algebras?
A: They arise as the endomorphism algebras of supersingular elliptic curves \( /F_p^2 \).

I don’t want to spoiler next week at all, but I cannot talk about quaternion algebras without a little bit of motivation first!
Example 3.3.1 What are we doing again? Let’s take

\[ K = \mathbb{F}_9 = \mathbb{F}_3[\alpha] = \mathbb{F}_3[x]/(x^2 - x - 1) \]

and

\[ E/K: y^2 = x^3 + ax = f(x), \]

simple eh? It’s supersingular as the \( j \)-invariant is 0 (and in characteristic 3). Alternatively, count points or even compute the Hasse invariant, the coefficient of \( p - 1 = 2 \) in \( f(x)^{(p-1)/2} \), yep, it’s 0.

We therefore have \( \#E(K) = 9 + 1 = 10 \) so we have a 2-torsion point \((P = (0,0))\) and any other point we can use to generate (will be 5 or 10 torsion). Let \( x = 1 \) so \( y^2 = 1 + \alpha = \alpha^2 \) so \( y = \pm \alpha \), say \( Q = (1, \alpha) \).

We have one endomorphism, \( p \)-power frobenius \( x \mapsto x^3, y \mapsto y^3 \). How to find another one?

Let’s compute an isogenous curve and see what happens! We will compute \( \psi: E \to E/\langle P \rangle = E' \). In general the formulae are a little annoying [88], when you have a 2-torsion point at \((0,0)\), not as bad:

\[ \psi = \left( x + \frac{f'(0)}{x}, y - \frac{y f'(0)}{x^2} \right) \]

\[ f'(0) = \alpha \]

so

\[ \psi = \left( \frac{x^2 + \alpha}{x}, \frac{y^2 - \alpha}{x^2} \right) \]

(aside: if \( g/h = (x^2 + \alpha)/x \) then \( (g/h)' = (g'h - gh')/h^2 = (2x^2 - (x^2 + \alpha))/x^2 = (x^2 - \alpha)/x^2 \), sanity check/fast computation?). The curve is then

\[ E': y^2 = x^3 + 0x^2 + (\alpha - 5\alpha)x + 0 = x^3 - ax. \]

I think really here we’re just recovering those classic formulae for 2-isogenies between curves with a rational 2 torsion point at \((0,0)\) (used in 2-descent).

\[ C: y^2 = x(x^2 + ax + b) \]
\[ D: v^2 = u(u^2 + a_1 u + b_1) \]
\[ \phi: C \to D \]
\[ (x, y) \mapsto ((y/x)^2, y - b y/x^2) \]
\[ \hat{\phi}: D \to C \]
\[ (u, v) \mapsto \left( \frac{1}{4} \left( \frac{v}{u} \right)^2, \frac{1}{8} (v - b_1 v/u^2) \right) \]

So far so good, our curve doesn’t look exactly the same, but it’s \( j \)-invariant is, so we are still in business. Is

\[ E \cong E'? \]

If we substitute \( x = \alpha^2 x, y = \alpha^3 y \) into \( E' \) we get

\[ \alpha^6 y^2 = \alpha^6 x^3 - \alpha^3 x \]
\[ y^2 = x^3 - \alpha^{-3} x = x^3 + ax, \]
call this map \( \iota \). Excellent, so to get \( \psi' \colon E \rightarrow E \) we compose \( \iota \circ \psi \).

\[
\iota \circ \left( \frac{x^2 + \alpha \cdot (x^2 - a)y}{x}, \frac{(x^2 - a)y}{x^2} \right) = \left( \frac{\alpha^2 x^2 + \alpha \cdot (x^2 - a)y}{x^2}, (-\alpha + 1) \frac{(x^2 - a)y}{x^2} \right)
\]

What happens to our other point \( Q \)? \( \psi'(Q) = (\alpha^2(1 + \alpha), \alpha^4(1 - \alpha)) = (-1, \alpha - 1) \)

\[
(0 : 0 : 1) \mapsto (0 : 1 : 0), \ (0 : 1 : 0) \mapsto (0 : 1 : 0), \ (1 : \alpha : 1) \mapsto (-1 : \alpha - 1 : 1),
\]

\[
(1 : -\alpha : 1) \mapsto (-1 : -\alpha + 1 : 1), \ (-1 : \alpha - 1 : 1) \mapsto (1 : -\alpha : 1),
\]

\[
(-1 : -\alpha + 1 : 1) \mapsto (1 : \alpha : 1), \ (\alpha : \alpha + 1 : 1) \mapsto (-1 : -\alpha + 1 : 1),
\]

\[
(\alpha : -\alpha - 1 : 1) \mapsto (-1 : -\alpha - 1 : 1), \ (-\alpha : -1 : 1) \mapsto (1 : -\alpha : 1), \ (-\alpha : 1 : 1) \mapsto (1 : -\alpha : 1)
\]

A word of caution: If you are very awake you may check and be led to believe that this is just the multiplication by \(-2\) isogeny on \( E \), its action on \( E(F_9) \) points is the same!!!!!! It’s not the same isogeny though so you can relax. Now we have an endomorphism ring with two elements, what are the relations between themselves, and each other?

As we quotiented by a rational 2-torsion point we have computed a factor of \( \pi - 1 \), the other factor comes from quotienting by 5-torsion. In fact we find. The frobenius has characteristic polynomial \( t^2 + 9 = (t + 3i)(t - 3i) \) \( \pi \) looks like \( 3i \). \( \psi \) has characteristic polynomial \( t^2 - 2t + 2 = (t + 1)^2 + 1 \), so \( \psi + 1 \) looks like \( \pm i \). \( \mp \psi = \pi - 1 \) \( \mp (i - 1) = 3i - 1 \), so \( 2 - i = 2 - (\psi + 1) = 1 - \psi \).

So what if we quotient by non-rational 2-torsion? Pass to the quadratic extension \( F_{3i} \), which we get from adjoining the other roots of \( 0 = x^3 + ax \) i.e. \( \pm \sqrt[3]{-a} \). Denote this extension \( F_3[\beta] \), \( (\beta^2 - 1)^2 = -a \). We can use Vélu again, it’s degree two still but a bit more ugh, you might need a computer from now on, actually I’ve been using one all along.

\[
\phi = \left( \frac{(\alpha + 1) x^2 + (-\beta^3 - \beta - 1) x}{x - (\beta^2 - 1)}, \frac{(-\alpha + 1) x^2 + (\beta^3 - \beta^2 + \beta - 1) x - 1}{(x - (\beta^2 - 1))^2} \right)
\]

doing a computation it looks like \( \phi \) satisfies \( \phi^2 - \phi + 2 \).

What are the relations between these? Hopefully they generate the endomorphism ring by now but without relations we are screwed! Do they commute? Computing \( \tau = \phi \psi - \psi \phi \) is relevant, if 0, commutative, otherwise not! Note that if they are algebraically dependant they must commute! In our example we can compute \( \tau^2 + 3 = 0 \)

Finish this example, compute the endomorphism ring as a recognisable quaternion order. Aside: I now believe Asra when she says not to use Vélu’s formulae for large degree!

Aside 2: Frobenius can be weird for supersingular curves, e.g. for

\[
y^2 = x^3 + x/F_9
\]

we have \( \pi = -3 \). Or

\[
y^2 = x^3 + 1/F_{25}
\]

we have \( \pi = -5 \)

Indeed one can find on the internet claims like, all elliptic curves over finite fields have extra endomorphisms because frobenius exists! Show by hand that \( y^2 + y = x^3/F_4 \) is supersingular and that frobenius is just the multiplication by \(-2\) map. PODASIP: this happens for all \( p^2 \)
3.3.1 Quaternion Algebras

Pretty much all of this material was ripped with the utmost love and affection from [89], check it out.

**Proposition 3.3.2** The theory of Quaternion algebras is very rich.

*Proof.* The above book is 800 pages long. ■

So now we have gone out into nature and observed a beautiful new species of algebra, time to catch it, pin it to a wall, dissect it to study it in detail. It might not look as pretty any more but it’s the way the science is done.

**Example 3.3.3** Hamilton’s quaternions. Hamilton’s quaternions $H$ were the first quaternion algebra to be discovered (citation needed). The structure is like two copies of $\mathbb{C}$ tensored together in some non-commuting way over $\mathbb{R}$. We have a real algebra with two generators $i, j$ s.t. $i^2 = j^2 = (ij)^2 = -1$ we let $k = ij$ for aesthetic reasons (note that these relations imply noncommutativity!). Like this we get a division algebra.

Quaternion algebras are a generalisation of this to other fields.

**Definition 3.3.4** Quaternion algebras. Let $F$ be a field (not characteristic 2), a quaternion algebra over $F$ is an algebra $B$ over $F$ for which there exist $a, b \in F^\times$ such that there is a basis

$$1, i, j, k \in B$$

such that

$$i^2 = a, j^2 = b, k = ij = -ji,$$

it is automatic that $k^2 = -ab$ from this.

We denote this particular quaternion algebra by $\left( \frac{a, b}{F} \right)$

**Example 3.3.5**

$$H = \left( \frac{-1, -1}{\mathbb{R}} \right).$$

**Example 3.3.6** What is

$$\left( \frac{1, 1}{F} \right) = \left( \frac{-1, -1}{F} \right)?$$

We have another way to come up with 4-dimensional non-commutative algebras over fields, matrices! Let

$$i = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix},$$

$$j = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix},$$

so

$$k = ij = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} = -ji$$

as required.

Call this example *split*, in analogy with quadratic theory, If $x^2 - N$ has a solution mod $p$ then $\left( \frac{N}{p} \right) = 1 = \left( \frac{1}{p} \right)$.

Note that if $a$ or $b \in (F^\times)^2$ then we can divide the corresponding basis element by $\sqrt{a}$ or whatever and find that $\left( \frac{a, b}{F} \right) = \left( \frac{1, b}{F} \right)$. This shows:
Proposition 3.3.7 After passing to the algebraic closure (or even the quadratic closure!) every quaternion algebra is split.

This is helpful as it allows us to work with non-split quaternion algebras as matrix algebras over a quadratic extension.

Example 3.3.8 \( H / \mathbb{R} \) can be seen as \( \text{Mat}_{2 \times 2}(\mathbb{R}(i)) = \text{Mat}_{2 \times 2}(\mathbb{C}) \), explicitly

\[
\begin{align*}
i &= i \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} = \begin{pmatrix} i & 0 \\ 0 & -i \end{pmatrix} \\
j &= i \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} = \begin{pmatrix} 0 & i \\ i & 0 \end{pmatrix}
\end{align*}
\]

please excuse the unfortunate notational clash here, I hope you agree it’s somewhat unavoidable. □

Here is a nice lemma I probably used implicitly already somewhere!

Lemma 3.3.9 An \( F \)-algebra \( B \) with \( F \)-algebra generators \( i, j \) satisfying \( i^2, j^2 \in F^\times \), \( ij = -ji \) is automatically a quaternion algebra (i.e. dimension 4).

Proof. Show linear independence of \( 1, i, j, ij \) (exercise). ■

Definition 3.3.10 Conjugate, trace and norm. Given a quaternion algebra \( B / F \) there is a unique anti-involution \( \tau : B \to B \), called conjugation.

With basis \( 1, i, j, ij \in \left( \frac{a, b}{F} \right) \) as above it is given as

\[
\overline{x + yi + zj + wij} = x - yi - zj - wij, \quad x, y, z, w \in F.
\]

As normal (heh) we define the (reduced) norm and trace

\[
\text{Norm } \alpha = \alpha + \overline{\alpha}, \quad \forall \alpha \in B
\]

\[
\text{Norm}(x + yi + zj + wij) = x^2 - ay^2 - bz^2 + abw^2
\]

and

\[
\text{Tr } \alpha = \alpha + \overline{\alpha}, \quad \forall \alpha \in B
\]

\[
\text{Tr}(x + yi + zj + wij) = 2x.
\]

3.3.1.1 Orders

In our example, while the endomorphism algebra \( \text{End}(E) \otimes \mathbb{Q} \) was of interest, the endomorphism ring \( \text{End}(E) \) was the more fundamental object. What is this? A quaternion ring?

Definition 3.3.11 Orders in quaternion algebras. Let \( B / \mathbb{Q} \) be a quaternion algebra, an order in \( B \) is a full rank sub-\( \mathbb{Z} \)-module that is also a subring. ■

Example 3.3.12 The Lipschitz order. \( B = \left( \frac{-1, -1}{\mathbb{Q}} \right) \) (Hamilton quaternions with \( \mathbb{Q} \)-coefficients) then we have an order

\[
\mathbb{Z} + \mathbb{Z}i + \mathbb{Z}j + \mathbb{Z}ij
\]

the Lipschitz order. □
Definition 3.3.13 Maximal. Orders are ordered (heh) with respect to inclusion, thus we get notions of maximality of orders etc.

Is the Lipschitz order maximal? NO! Whats going on? \( \mathbb{Z}[i] \) is maximal in \( \mathbb{Q}(i) \) after all. Consider

\[
i + j + k, \quad (i + j + k)^2 = i^2 + j^2 + k^2 + ij + jk + ki + 0
\]

so we have a \( \mathbb{Z}[\sqrt{-3}] \) lurking inside \( \left( \frac{-1}{\mathbb{Q}} \right) \), quaternion algebras are not everything they appear to be at first sight! \( \mathbb{Z}[\sqrt{-3}] \) is non-maximal and we must add \( \sqrt{-3}/2 \) to make it so. Lets add this in the quaternion setting:

Example 3.3.14 The Hurwitz order. Let \( B = \left( \frac{-1}{\mathbb{Q}} \right) \), then

\[
\mathbb{Z} + Zi + Zj + \mathbb{Z} \left( \frac{i + j + k}{2} \right)
\]

is an index two suborder of the Lipschitz order, called the **Hurwitz order**, this is maximal.

Warning, just because \( \sqrt{-3} \in \left( \frac{-1}{\mathbb{Q}} \right) \) we do not have \( \left( \frac{-1}{\mathbb{Q}} \right) = \left( \frac{-1}{\mathbb{Q}} \right) \)!

Example 3.3.15 /Exercise. Show that the elliptic curve from the exercise earlier

\[
y^2 + y = x^3/\mathbb{F}_2
\]

has endomorphism algebra the Hurwitz order.

Solution. Here is what me and Angus think, we have the 2-power frobenius \( \pi \) a degree 2 isogeny whose square is minus 2, we also have the isogeny \( \phi : x \mapsto \zeta_3 x, \quad y \mapsto y \) which is in fact an automorphism (degree 1) and satisfies \( \phi^2 + \phi + 1 = 0 \). The relation between these two isogenies is that \( \pi \phi = \phi^2 \pi : x \mapsto \zeta_3 x^2, \quad y \mapsto y^2 \).

Inside the Hurwitz order we have some candidates for an element whose square is \(-2\) there are a few, coming in two types \( a + b \) for \( a \neq b \in \{ i, j, k \} \) and \( a - b \) for \( a \neq b \in \{ i, j, k \} \), we choose the second type (why? because it works and the other doesn’t), let \( p = i + j \) for concreteness. We also have a cube root of unity in the Hurwitz order, it is \( f = (-1 + i + j + k)/2 \).

We can calculate now what \( pf \) and \( f^2 p \) are, they both come out to be \(-i + k\), some other square root of minus 2, which makes sense because degree is multiplicative. Anyway this is consistent with the endomorphism ring but there is a slight problem, the order generated here has discriminant 6, so its non-maximal as we know its contained in the Hurwitz order but the discriminant is higher, Deuring tells us we have to get a maximal order so we need something extra.

Warning, there is no such thing as the maximal order of a quaternion algebra! Rather there are multiple maximal orders due to non-commutativity, e.g. if \( \mathcal{O} \) is a maximal order then so is

\[
a \mathcal{O} a^{-1} \neq \mathcal{O}.
\]

Normally when we have unique maximal things with a certain property, its because we can always take spans/unions and they still have that property.

This is no longer true here, the sum of two elements with integral trace and norm need not remain so, nor the product.
We can define discriminants of orders which like normal give a hint as to their maximality

\[ O = \mathbb{Z} + \mathbb{Z}i + \mathbb{Z}j + \mathbb{Z}ij \subseteq \left( \frac{a, b}{\mathbb{Q}} \right) \]

\[ \text{disc } O = d(1, i, j, ij) = \det \begin{pmatrix} 2 & 0 & 0 & 0 \\ 0 & 2a & 0 & 0 \\ 0 & 0 & 2b & 0 \\ 0 & 0 & 0 & -2ab \end{pmatrix} = (4ab)^2 \]

**Exercise 3.3.16** Find the discriminant of the Lipschitz order.

### 3.3.1.2 Local theory

**Theorem 3.3.17** Over a local field \( F \neq \mathbb{C} \) there is a unique division quaternion algebra \( B/F \) up to \( F \)-isomorphism. If \( F = \mathbb{Q}_p, p \neq 2 \) then this is \( \left( e, p \right) \mathbb{Q}_p \) for \( e \) any quadratic non-residue mod \( p \).

This is saying that any quadratic extension of \( F \) embeds into \( B \)!

**Definition 3.3.18** Split and ramified quaternion algebras. Let \( B/\mathbb{Q}_v \) be a quaternion algebra, we say that \( B \) is

\[ \begin{cases} \text{split} & \text{if } B \cong M_2(\mathbb{Q}_v) = \left( \frac{1, -1}{\mathbb{Q}_v} \right) \\ \text{ramified} & \text{otherwise} \end{cases} \]

Correspondingly we say that \( B/\mathbb{Q} \) is split/ramified at a place \( v \) if the corresponding \( B \otimes \mathbb{Q}_v \) has that property.

The terminology definite for quaternion algebras ramified at infinity is also used (i.e. for which \( B \otimes \mathbb{R} = \mathbb{H} \)).

**Theorem 3.3.19** Albert-Brauer-Hasse-Noether. Let \( B/F \) be a quaternion algebra over a number field \( F \) (or any central simple algebra), if \( B \) splits at every place \( v \) of \( F \) then \( B \) is a matrix algebra \( M_d(F) \).

In fact:

**Theorem 3.3.20** Two quaternion algebras are isomorphic if and only if they are isomorphic everywhere locally, i.e. if the set of places at which they ramify is the same.

Warning: Quaternion algebras may not be ramified where you think they are?

Knowing the ramification of a quaternion algebra \( \mathbb{Q} \) is enough to identify it uniquely, in fact we have the following theorem

**Theorem 3.3.21** Main Theorem [89, 14.1.3]. There is a sequence of bijections

\[ \{ \text{quaternion algebras } B/\mathbb{Q} \} / \text{isom.} \]

\[ S \mapsto \text{unique } B \text{ ramified at exactly } S \nmid D \mapsto \{ p : B \text{ is ramifies at } p \} \]

\[ \{ S \subseteq \text{places of } \mathbb{Q}, 2 \nmid \# S \} \]

\[ D \mapsto \{ p|D \} \cup \{ \infty \} \text{ if } 2 \nmid \omega(D) \mid S \mapsto \prod_{p \in S, p \neq \infty} p \]

\[ \{ D \in \mathbb{Z}_{>0} \text{ squarefree} \} \]
Sometimes however we want generators and relations not just ramification information: (As we will only care about discriminant $p$ quaternion algebras)

In our setting the relevant theorem is:

**Theorem 3.3.22** Pizer. Let $\mathbb{Q}_{p,\infty}$ be the unique quaternion algebra ramified at $p, \infty$, let $q \equiv 3 \pmod{4}$ be such that $\left(\frac{p}{q}\right) = -1$, then

$$
\mathbb{Q}_{p,\infty} \cong \begin{cases}
\left(\frac{-1}{Q}\right) & \text{if } p \equiv 2 \pmod{4}, \\
\left(\frac{-1-p}{Q}\right) & \text{if } p \equiv 3 \pmod{4}, \\
\left(\frac{-2-p}{Q}\right) & \text{if } p \equiv 1 \pmod{8}, \\
\left(\frac{-p-q}{Q}\right) & \text{if } p \equiv 5 \pmod{8}.
\end{cases}
$$

Ibukiyama has given a nice description of a maximal order in such. Here are some nice references:

### 3.4 The Deuring Correspondence (Maria Ines)

References:

1. Voight ch. 16,17,42

3.4.1 Background: Ideals and Ideal classes

Let \( B/\mathbb{Q} \) be a quaternion algebra and \( \mathcal{O} \subseteq B \) be an order. If \( I \subseteq B \) is a lattice, we can define \( \mathcal{O}_L(I) = \{ \alpha \in B : \alpha I \subseteq I \} \). This is an order, it’s the left order of \( I \) similarly can define \( \mathcal{O}_R(I) \).

**Definition 3.4.1** A left (resp. right) fractional ideal is a lattice \( I \subseteq B \) s.t. \( \mathcal{O} \subseteq \mathcal{O}_L(I) \) resp \( \mathcal{O} \subseteq \mathcal{O}_R(I) \).

**Definition 3.4.2** Compatibility. For lattices \( I, J \subseteq B \) we say \( I \) is compatible with \( J \) if \( \mathcal{O}_R(I) = \mathcal{O}_L(J) \).

A lattice \( I \) is invertible if there is a lattice \( I' \subseteq B \) s.t.

\[
II' = \mathcal{O}_L(I) = \mathcal{O}_R(I')
\]

\[
I' I = \mathcal{O}_L(I') = \mathcal{O}_R(I)
\]

with both products compatible.

**Proposition 3.4.3** Let \( \mathcal{O} \subseteq B \) be a maximal order then every left or right fractional \( \mathcal{O} \)-ideal is invertible.

**Definition 3.4.4** Principal ideals. An ideal of the form \( I = \mathcal{O}_L(I) \alpha = \alpha \mathcal{O}_R(I) \) is a principal ideal.

**Fact 3.4.5** \( I \) is invertible with \( I^{-1} = \alpha^{-1} \mathcal{O}_L(I) = \mathcal{O}_R(I) \alpha^{-1} \).

**Definition 3.4.6** Reduced norms. Let \( I \subseteq B \) be a fractional ideal the reduced norm of \( I \) is the positive generator of the fractional ideal generated by

\[
\{ \text{nr}(a) : a \in I \}
\]

in \( \mathbb{Q} \). We denote it \( \text{nr}(I) \).

**Ideal classes.** **Definition 3.4.7** Ideal classes. Two left fractional ideals \( I, J \subseteq B \) are in the same left class

\[
I \sim_L J
\]

if \( \exists \alpha \in B^\times \) s.t. \( \alpha I = J \). Equivalently if \( \mathcal{O}_L(I) = \mathcal{O}_L(J) \) and \( I \sim J \) as left modules over this order. \( \sim_L \) is an equivalence relation \([I] \) is the class of \( I \). If \( I \) is invertible then every \( J \in [I] \) is invertible, and then we say \([I]_L \) is invertible.

**Definition 3.4.8** Class sets. Let \( \mathcal{O} \subseteq B \) be an order. The left class set of \( \mathcal{O} \) is

\[
\text{Cls}_L \mathcal{O} = \{ [I]_L : I \subseteq B \text{ is invertible and } \mathcal{O}_L(I) = \mathcal{O} \}
\]

its a pointed set with distinguished element \([\mathcal{O}]_L \).

**Theorem 3.4.9** Let \( \mathcal{O} \subseteq B \) be an order. then \( \text{Cls}_L \mathcal{O} \) is finite. We call \#\( \text{Cls}_L \mathcal{O} \) the left class number of \( \mathcal{O} \).

**Types of orders.** Let \( \mathcal{O}, \mathcal{O}' \subseteq B \) be orders.

**Definition 3.4.10** We say \( \mathcal{O}, \mathcal{O}' \) are of the same type if \( \exists \alpha \in B^\times \) s.t. \( \mathcal{O}' = \alpha^{-1} \mathcal{O} \alpha \). \( \mathcal{O}, \mathcal{O}' \) are locally of the same type if \( \mathcal{O}_p, \mathcal{O}'_p \) are of the same type for all primes in \( \mathbb{Z} \cup \{ \infty \} \). \( \mathcal{O} \) is connected to \( \mathcal{O}' \) if there exists an invertible fractional \( \mathcal{O}, \mathcal{O}' \)-ideal.
Lemma 3.4.11 \( O, O' \) are of the same type iff they are isomorphic as \( \mathbb{Z} \)-algebras. 
\( O, O' \) are connected iff they are locally of the same type.

Definition 3.4.12 Let \( O \subseteq B \) be an order.

1. The genus \( \text{Gen}(O) \) of \( O \) is the set of orders in \( B \) connected to \( O \).
2. The type set \( \text{Typ}(O) \) of \( O \) is the set of \( \mathbb{Z} \)-algebra isomorphism classes of orders in \( \text{Gen}(O) \).

Lemma 3.4.13 The set map \( \text{Cls}_L(O) \rightarrow \text{Typ}(O) \)
\[
[I]_L \mapsto \text{class of } O_R(I)
\]
is surjective.

Remark 3.4.14
1. Any two maximal orders in \( B \) are connected.
2. In particular there are only finitely many conjugacy classes of maximal orders in \( B \).

Example 3.4.15 Voight 17.6.3. Let
\[
B = \left( \frac{-1,-23}{\mathbb{Q}} \right)
\]
Then \( O = \mathbb{Z} + \mathbb{Z}i + \mathbb{Z}i^{\frac{1+i}{2}} + \mathbb{Z}i^{\frac{1+i}{2}} \) is a maximal order and
\[
\text{Typ}(O) = \{ [O], [O_2], [O_3] \}.
\]

3.4.2 The Deuring Correspondence

Fix a prime \( p \), let \( E \) be an elliptic curve over \( \mathbb{F}_q = \mathbb{F}_{p^n} \).

Lemma 3.4.16 The endomorphism algebra \( \text{End}(E)_\mathbb{Q} = \text{End}(E) \otimes \mathbb{Q} \) of \( E \) is either \( \mathbb{Q} \) an imaginary quadratic field or a definite quaternion algebra \( / \mathbb{Q} \).

Theorem 3.4.17 Deuring, this proof by Lenstra. Let \( E/\mathbb{F}_q \) be a s.s. e.c. (i.e. assume \( \text{End}(E) \otimes \mathbb{Q} \) is a quaternion algebra). Then \( \text{Ram}(B) = \{ p, \infty \} \) and \( O = \text{End}(E) \) is a maximal order in \( B \).

Proof. Let \( n > 0 \) be prime to \( p \). Then
\[
E[n] \cong \mathbb{Z}/n \oplus \mathbb{Z}/n
\]
as groups so \( \text{End}(E[n]) \cong M_2(\mathbb{Z}/n) \).

Claim: The structure map \( O/nO \rightarrow \text{End}(E[n]) \) is an isomorphism.

Check: suppose \( \phi \in O \) kills \( E[n] \), then since \( \phi \) is separable then \( \exists \psi \in O \) s.t. \( \phi = n\psi \). Hence \( \phi = 0 \in O/n \). This gives injectivity.

As both rings are finite with the same order \( n^4 \) we have an isomorphism.

Since \( O \) is a free \( \mathbb{Z} \) module
\[
O_1 = O \otimes Q_1 = \lim_{n} O \otimes \mathbb{Z}/l^n
\]
\[
\lim_{n \to \infty} \frac{O}{l^n} \cong \lim_{n \to \infty} \text{End}(E[l^n]) \\
\cong \text{End}_{\mathbb{Z}} \cong M_2(\mathbb{Z})
\]
for any \(l \neq p\) primes. This is an isomorphism as \(\mathbb{Z}\)-algebras.

In particular \(O_l\) is maximal in \(B_l \cong M_2(\mathbb{Q}_l)\) and \(B\) is split at \(l\) for all \(l \neq p\). Since \(B\) is definite, it follows from the classification theorem that \(\text{Ram}(B) = \{p, \infty\}\).

Fact: \(O_p\) is maximal in \(B_p\) (thm 42.1.9 of Voight).

\[O\text{ is maximal in } B \text{ because it is locally maximal.} \]

Theorem 3.4.18 Deuring correspondence.

\[
\{\text{maximal orders } O \subseteq B_{p,\infty}\} / \sim \leftrightarrow \{j \text{ s.s. } \in \mathbb{F}_{p^2}\} / \text{Gal}(\mathbb{F}_{p^2}/\mathbb{F}_p).
\]

Proof. Voight 42.4.7.

Definition 3.4.19 Let \(I \subseteq O = \text{End}(E)\) be an integral left \(O\)-ideal with \((\text{nr}(I), p) = 1\). Define

\[E[I] = \{P \in E(\mathbb{F}_p) : \alpha(P) = 0 \forall \alpha \in I\}\]

Then there is a separable isogeny

\[\Phi_I : E \to E/E[I]\]

with \(\ker \Phi_I = E[I]\).

\[\text{Fact 3.4.20 } \deg(\Phi_I) = \text{nr}(I)\]

Proposition 3.4.21 The association \(I \mapsto \phi_I\) is a 1-1 correspondence provided that \((\deg \phi_I, p) = 1\).

3.4.3 Applications to SIG crypto

Problem 3.4.22 Constructive Deuring correspondence. Given a maximal order \(O \subseteq B_{p,\infty}\) return a s.s. \(j\)-invariant \(j\) s.t. \(O \cong \text{End}(E_j)\).

Problem 3.4.23 Inverse Deuring correspondence. Given a supersingular \(j\) invariant \(j\), compute a maximal order \(O \subseteq B_{p,\infty}\) s.t. \(O \cong \text{End}(E_j)\). \(O\) is described by a \(\mathbb{Z}\)-basis.

Problem 3.4.24 Endomorphism ring computation problem. Given a supersingular \(j\) invariant \(j\), \(\text{End}(E_j)\). \(\text{End}(E_j)\) should be returned as 4 or 3 rational maps that form a \(\mathbb{Z}\)-basis. Their representation should be efficient in storage and in evaluation time at points.

Remark 3.4.25

1. Problem 1 can be solved in polynomial time, (Prop. 14 in Petit-Lauter).

2. P2 and P3 are polynomially equivalent but this isn’t obvious (P-L sec.3.1 and 3.2)

3. There is no known efficient algorithm to solve P3.

Recall: the (Charles-Goren-Lauter) CGL hash function is preimage resistant iff given 2 s.s. \(j\)-invariants \(j_1, j_2\) its computationally hard to compute a positive integer \(e\) and an isogeny \(\phi : E_{j_1} \to E_{j_2}\) of degree \(l^e\).
Proposition 3.4.26 Assume there’s an efficient algorithm to solve P3. Then there is an efficient algorithm to solve the preimage problem for the CGL hash function.

Proof. Algorithm

Input: two s.s. \( j \)-invariants \( j_s, j_t \in \mathbb{F}_{p^2} \).

Output: sequence of \( j \)-invariants

\[ j_s, \ldots, j_0, \ldots, j_t. \]

1. Compute \( \text{End}(j_s), \text{End}(j_t) \).

2. Compute \( O_s \simeq \text{End}(E_{j_s}), O_t \simeq \text{End}(E_{j_t}) \).

3. Compute ideals \( I_s \) and \( I_t \) connecting \( O_0 \) to \( O_s, O_t \).

4. Compute ideals \( J_s \in [I_s], J_t \in [I_t] \), with norms \( l^o_s, l^o_t \).

5. For \( J \in \{ J_s, J_t \} \) and corresponding \( E \in \{ E_s, E_t \} \) and \( e \in \{ e_s, e_t \} \) compute \( j_i = O_0 p^2 + O_i l^e \) for \( i = 0, \ldots, e \). For \( i = 0, \ldots, e \) compute \( K_i \in [J_i] \), with powersmooth norm. Translate \( K_i \) into an isogeny \( \phi : E_0 \rightarrow E_i \).

Deduce a sequence \( (j_0, j(E_1), \ldots, j(E) = j_e) \).

6. Return \( (j(E_s), \ldots, j_0, \ldots, j(E_t)) \).

Except for step 1 everything can be done efficiently. ■

Remark 3.4.27 The converse is also true.
Chapter 4

\( p \)-divisible groups

These are notes for the short-lived BUNTES Fall 2018 part II, the topic is \( p \)-divisible groups.

References:

1. Tate
2. Schatz

4.1 \( p \)-divisible groups (Sachi)

Why study \( p \)-divisible groups (Jacob Stix).

1. Analyse local \( p \)-adic galois action on \( p \)-torsion of elliptic curves, Serre’s open image theorem.

\[ \phi_l : G_K \to \text{Aut}[I] \]

Surjective for almost all \( l \).

2. Tool for representing \( p \)-adic cohomology, e.g \( p \)-adic hodge theory.

3. Describe local properties of moduli spaces of abelian varieties which map to moduli spaces of \( p \)-divisible groups which can be described by semilinear algebra (Serre-Tate).

4. Explicit local CFT via Lubin-Tate formal groups describing wildly ramified abelian extensions.

5. The true fundamental group in characteristic \( p \) must include infinitesimal group schemes, \( p \)-divisible groups enter through their Tate modules.

Detour, schemes. There is an (anti)-equivalence of categories

\[ \{ \text{ring} \} \leftrightarrow \{ \text{affine schemes} \}. \]

Moral whatever a scheme is the data of a ring is enough to specify it + homs

\[ \text{Hom}_{\text{Ring}}(B, A) \leftrightarrow \text{Hom}_{\text{Aff}}(\text{Spec } A, \text{Spec } B) \]

to specify a base field or base ring play a similar game with \( R \)-algebras and \( R \)-schemes.
Yoneda, schemes are functors: Let $R[T_1, \ldots, T_n]$ be a polynomial ring over $R$, we want solutions to

$$f_1 = f_2 = \cdots = f_m = 0$$

with coefficients in $A$ this is asking for a map

$$R[T_1, \ldots, T_n]/(f_i) \to A$$

same as

$$\text{Hom}_{R\text{-alg}}(R[T_1, \ldots, T_n]/(f_i), A)$$

functor $A$ to this is a functor from $R$-algs to sets.

**Definition 4.1.1** For any affine scheme $A = \text{Spec } B$ we attach a functor $h_X$ from $\text{Sch}^{\text{op}}$ to sets, sending $\text{Spec } S \mapsto \text{Hom}_{\text{Sch}}(\text{Spec } S, X) = \text{Hom}_{\text{Ring}}(B, S) = h_X(\text{Spec } S)$. spec points of $X$.

**Example 4.1.2**

$$A^n = \text{Spec } \mathbb{Z}[T_1, \ldots, T_n]$$

$$A^n(T) = \text{Hom}_{\text{Sch}}(T, A^n) = \text{Hom}_{\text{Ring}}(\mathbb{Z}[T_1, \ldots, T_n], S) \cong S^n$$

**Example 4.1.3**

$$E \colon \text{Spec } k[x, y]/(y^2 - (x^3 + ax + b)), k = \mathbb{Q}$$

$E(\mathbb{Q}(i)) = \mathbb{Q}(i)$ points, choosing $x, y$ satisfying weierstrass equation.

Suppose $h_X : \text{Sch}^{\text{op}} \to R$ factors through $\text{Grp} \to \text{Set}$ then this is a group scheme.

**Example 4.1.4**

$$G_a = \text{Spec } k[t]$$

$$S \mapsto \text{Hom}(k[t], S) \cong (S, +)$$

**Example 4.1.5**

$$G_m = \text{Spec } k[t, t^{-1}]$$

$$S \mapsto \text{Hom}(k[t, t^{-1}], S) \cong (S^\times, \cdot)$$

**Example 4.1.6**

$$\mu_n = \text{Spec } k[t]/(t^n - 1)$$

**Example 4.1.7**

$$\alpha_{p^n} = \text{Spec } k[t]/(t^{p^n})$$

char $k = p$

Cartier Duality $G$ is a finite group scheme $/R$ there is a dual $G^*(T) = \text{Hom}(G_T, G_m)$

$R$-scheme $T$

$$G \cong (G^*)^*$$

**Example 4.1.8**

$$\mu_{p^n} \leftrightarrow \mathbb{Z}/p^n$$
**Definition 4.1.9** Let \( p \) be a prime and \( h \) a non-negative integer. A \( p \)-divisible group of height \( h \) is an inductive system

\[
(G_v, i_v)
\]

where each \( G_v \) is a group scheme \( /R \) of size \( p^{vh} \)

\[
i_v: G_v \to G_{v+1}
\]

identifies \( G_v \) with kernel of multiplication by \( p^v \).

\[
0 \to G_v \xrightarrow{i_v} G_{v+1} \xrightarrow{[p^v]} G_{v+1}
\]

**Remark 4.1.10** We can show that \( G_\mu, G_v \) are two levels then

\[
0 \to G_\mu \xrightarrow{i_\mu} G_{\mu+v} \xrightarrow{[p^v]} G_{\mu+v}
\]

so

\[
0 \to G_\mu \to G_{\mu+v} \to G_v \to 0.
\]

The connected etale sequence

A finite flat group scheme \( G \) over a henselian local ring \( R \) admits a (functorial) decomposition

\[
0 \to G^\circ \to G\to G^{et} \to 0
\]

connected and etale.

There is an equivalence of categories between finite etale gp scheme \( /R \) and its continuous \( \text{Gal}(\overline{k}/k) \) modules when \( R = k \) is a field.

**Definition 4.1.11** An \( n \)-dimensional formal lie group \( /R \) is the formal power series ring

\[
A = R[[x_1, \ldots, x_n]]
\]

with a suitable co-multiplication structure.

\[
m^* : A \to A \hat{\otimes} A
\]

require

1. \( F(X, 0) = F(0, X) = X \)

2. \( F(X, F(Y, Z)) = F(F(Y, Z), X) = X \)

3. \( F(Y, Z) = F(Z, Y) \)

\[
\psi
\]

Let \( \psi \) denote multiplication by \( p \) in \( A \) then \( A \) is divisible if \( \psi \) is an isogeny (surj. with finite kernel). Alternatively \( A \) is a finite free \( \psi(A) \)-module.

**Theorem 4.1.12** Let \( R \) be a complete noetherian local ring with residue characteristic
$p > 0$. We have an equiv of cats

\[ \text{conn. } p \text{-div gps } \leftrightarrow \text{ div. formal lie groups }/\mathbb{R} \]

Example 4.1.13

\[ \mathbb{G}_m(p), \ F(X) = Y + Z + YZ \]

\[ \square \]

Example 4.1.14  $E$ ordinary elliptic curve $/\overline{\mathbb{F}}_p$

\[ E[p](\overline{\mathbb{F}}_p) \]

is non-empty

\[ E[p] = E[p]^\circ \times E[p]^{\text{et}}. \]

etale group schemes over alg. closed fields are constant

\[ E = E[p]^\circ \times A \]

It can’t be entirely etale $[p]$ would be etale but this induces the 0 map on tangent space so $E[p]^\circ \neq 0$.

\[ |E[p]| = p^2 \]

so each order $p$.

\[ A = \mathbb{Z}/p \]

$E$ is cartier self dual

\[ A^* = \mu_p = E[p]^\circ \]

Induct for $E[p^n]$.  \[\square\]
Chapter 5

Shimura varieties

These are notes for BUNTES Fall 2018 part III, the topic is Shimura varieties
Outline:
1. Modular curves/forms
2. Abelian varieties
3. Hodge structures
4. Definition/construction of Shimura varieties

References:
• Weinstein, Lecture Notes on Shimura varieties
• Milne, Introduction to Shimura Varieties

5.1 Modular curves (Aash)

Definition 5.1.1 Lattices. A lattice is a free abelian group of rank 2
\[ \Lambda \otimes \mathbb{R} \rightarrow \mathbb{C} \]
is an isomorphism
\[ \Lambda = \mathbb{Z}[\alpha] \oplus \mathbb{Z}[\beta] \]
if
\[ \Lambda = \gamma \Lambda', \gamma \in \mathbb{C} \]
then we say the two lattices are homothetic.

Any lattice is homothetic to one of the form
\[ \Lambda = (1, \tau) \]
as we can take a positively oriented basis we have that all such are equivalent to
\[ \tau \in \mathbb{H} = \{ z \in \mathbb{C} : \Im(z) > 0 \} . \]

So there is a bijection between \( \mathbb{H} \) and ordered bases of lattices.
\( SL_2(\mathbb{Z}) \) acts on \( \mathbb{H} \) and the action corresponds to changing bases.
The action of $\text{PSL}_2(\mathbb{Z})$ is faithful. $i, \rho = e^{\pi i/3}$ have non-trivial stabilisers

$$\text{Stab}_i = \langle S \rangle = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}$$

$$\text{Stab}_\rho = \langle TS \rangle, \ T = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$$

We can determine the order of elements by looking at the characteristic polynomials.
We then have

$$Y(1) = \text{SL}_2(\mathbb{Z}) \backslash H$$

a complex manifold and

$$j : Y(1) \to \mathbb{C}$$

is an isomorphism.
We have a fundamental domain for this action

$$D = \{ z \in \mathbb{C} : |z| \geq 1, |\Re(z)| \leq \frac{1}{2} \}$$

$Y(1)$ is Hausdorff because the action is properly discontinuous.
Care must be taken around the elliptic points (those with larger stabiliser),
to define the complex structure.
The extended upper half plane

$$H^* = H \cup \mathbb{P}^1(\mathbb{Q})$$

also has an $\text{SL}_2(\mathbb{Z})$ action via fractional linear transformations, which is proper.
We can define a basis of neighbourhoods around the cusps by transforming them to the cusp $\infty$ where we can use the basis of neighbourhoods given by

$$H_N = \{ z \in H : |\Im(z)| > N \}.$$

The parameter $q$ around $\infty$ is defined as $e^{2\pi i z/N}$ for some $N \in \mathbb{Z}$, $q$ is fixed
by $T$.
We can quotient by the action of $\text{SL}_2(\mathbb{Z})$ on $H^*$ to get

$$X(1) = \text{SL}_2(\mathbb{Z}) \backslash H^*$$

which is now compact, genus 0, which matches up with $Y(1)$ having $\mathbb{C}$ points
$\mathbb{C}$ earlier.
If $X$ is a projective curve then $X(\mathbb{C})$ has the structure of a compact Riemann
surface. If $S$ is such a surface then there exists a unique up to isomorphism $X$
with $X(\mathbb{C}) = S$.
The meromorphic functions on $S$ are the function field of $X$ and there is a
correspondence

Compact Riemann surfaces $\leftrightarrow$ Smooth proj. curves

Given a finite index subgroup of $\text{SL}_2(\mathbb{Z})$ we can do something similar to
obtain

$$\Gamma \backslash H.$$

One of the most prominent examples of such a subgroup is

$$\Gamma(N) = \left\{ \gamma \in \text{SL}_2(\mathbb{Z}) : \gamma \equiv \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \pmod{N} \right\}$$
along with
\[ \Gamma_1(N) = \left\{ \gamma \in \text{SL}_2(\mathbb{Z}) : \gamma \equiv \begin{pmatrix} 1 & * \\ 0 & 1 \end{pmatrix} \pmod{N} \right\} \]
\[ \Gamma_0(N) = \left\{ \gamma \in \text{SL}_2(\mathbb{Z}) : \gamma \equiv \begin{pmatrix} * & * \\ 0 & * \end{pmatrix} \pmod{N} \right\}. \]

\( \Gamma(N) \) is normal inside \( \text{SL}_2(\mathbb{Z}) \) and \( \Gamma_1(N) \) is normal inside \( \Gamma_0(N) \).

The aforementioned equivalence of categories gives us a smooth projective curve for each of these examples.

In fact one can find a smooth projective curve with \( \mathbb{Q} \)-coefficients realising each of these Riemann surfaces.

For \( \Gamma_0(N) \backslash \mathbb{H} \)
we have the function \( j(z) \) from before, but also \( j(Nz) \) which is still a function on the quotient now as
\[
j(N\gamma z) = j \left( N \frac{az + b}{cz + d} \right)
= j \left( N \frac{az + b}{c'Nz + d} \right)
= j \left( \frac{aNz + bN}{c'Nz + d} \right)
= j(\gamma'Nz)
= j(Nz)
\]

We can therefore let
\[
g = \prod_{\gamma} (Y - j(\gamma Nz))
\]
the product over the cosets of \( \Gamma_0(N) \subseteq \text{SL}_2(\mathbb{Z}) \).

The coefficients of \( g \) are meromorphic functions on \( X(1) = \mathbb{C}[j] \). So we have
\[ g(Y) = F(j(z), Y) \]
and
\[ g(j(Nz)) = F(j(z), j(Nz)) = 0 \]
then \( F(X, Y) \) is irreducible and has integer coefficients.

Then the curve \( X_0(N) \) whose function field is
\[ \mathbb{Q}[X, Y]/F(X, Y) \]
so \( U \subseteq X_0(N) \) is isomorphic to an affine variety defined by
\[ F(X, Y) = 0 \setminus \text{singular pts} \]
\[ \Gamma_0(N) \backslash \mathbb{H} \to U(\mathbb{C}) \]
\[ z \mapsto (j(z), j(Nz)) \]
\[ j(\gamma z) = z \forall z \text{ iff } \gamma \in \text{SL}_2(\mathbb{Z}). \]
If for \( z = z_1, z_2 \) have \( (j(z_1), j(Nz_1)) \) equal then \( z_1, z_2 \) are in the same \( \Gamma_0(N) \) orbit.

We can do similar for \( \Gamma_1 \) but only over \( \mathbb{Q}(\zeta_N) \).
Elliptic curves. Several definitions:

1. Smooth proj. curve genus 1 with a rational point.
2. Smooth curve given by Weierstrass eqn.
   \[ y^2 + a_1 xy + a_3 y = x^3 + a_2 x^2 + a_4 x + a_6. \]
3. Complex torus of dimension 1.

Over \( \mathbb{C} \) at least all are equivalent.

To get the Weierstrass equation from the curve we use Riemann-Roch to see that
\[
H(1[0]) = 1, \quad H(2[0]) = 2, \quad H(3[0]) = 3
\]
So we call a generator of \( H(2[0]) \setminus H([0]) \) the function \( x \) same for \( y \) and \( H(3[0]) \), now in \( H(6[0]) \) we have
\[
1, x, y, x^2, xy, y^2, x^3
\]
so there is a linear relation among these, giving the Weierstrass equation.

To get the equation for a torus we use the Weierstrass \( \wp \) function.

5.2 Modular forms (Asra)

Last time we saw the \( j \)-function, which was \( \text{SL}_2(\mathbb{Z}) \)-invariant, this is quite a strong condition, and in fact \( j \) is pretty much all we get under this condition. So instead we weaken this somewhat to some other variance property.

If \( w = f(z) \, dz \) on \( \mathbb{H} \) and \( f(z) \) is meromorphic. \( \gamma \in \Gamma \) then
\[
f(\gamma z)d(\gamma z) = f(\gamma z)d \left( \frac{az + b}{cz + d} \right)
\]
\[
= f(\gamma z) \left( \cdots d (cz + d)^2 \right)
\]
so we get a condition
\[
f(\gamma z) = (cz + d)^2 f(z)
\]
this is how we come to:

**Definition 5.2.1** A holomorphic function \( f: \mathbb{H} \to \mathbb{C} \) is a weakly modular function for \( \Gamma \) of weight \( k \) if
\[
f(\gamma z) = (cz + d)^k f(z) \forall \gamma = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \Gamma.
\]

\[\Diamond\]

**Remark 5.2.2** If \( -I \in \Gamma \) and \( k \) odd
\[
f(-z) = -f(-z)
\]
so in this setting we only have interesting behaviour for even \( k \).

If \( \Gamma \) is a congruence subgroup of level \( N \) we have
\[
\begin{pmatrix} 1 & N \\ 0 & 1 \end{pmatrix} \in \Gamma
\]
gives you a \( q \)-expansion
\[
q = e^{2\pi i z}
\]
\[ f(z) = \sum_{m \in \mathbb{Z}} a_m q^{m/N}. \]

\( f \) is holomorphic at \( \infty \) if \( a_m = 0 \) for \( m < 0 \).

\( f \) is holomorphic at all cusps if \( f(\gamma z)(cz + d)^k \) is holomorphic at \( \infty \) for all \( \gamma \in \text{SL}_2(\mathbb{Z}) \).

**Example 5.2.3** Cusps for \( \Gamma_0(p) \), we know we have \( \infty \), what is the orbit of this?

\[ \gamma \in \Gamma_0(p), \quad \gamma = \begin{pmatrix} a & b \\ cp & d \end{pmatrix} \]

\[ \gamma \infty = \frac{a}{cp} \]

so anything with a \( p \) in the denominator is equivalent to \( \infty \), what about the rest?

\[ \gamma 0 = \frac{b}{d}, \quad \gcd(b, d) = 1, \]

so we have two cusps.

**Definition 5.2.4** Modular forms. A modular form is a weakly modular function that is holomorphic at all the cusps.

**Example 5.2.5** Eisenstein series

\[ G_k(z) = \sum_{m, n \in \mathbb{Z}}' \frac{1}{(mz + n)^k} \]

is a modular form of weight \( k > 2 \) for \( \text{SL}_2(\mathbb{Z}) \).

\[ \lim_{\text{im } z \to \infty} G_k(z) = \lim_{\text{im } z \to \infty} \sum_{m, n \in \mathbb{Z}}' \frac{1}{(mz + n)^k} = \sum_{n \in \mathbb{Z}} \frac{1}{n^k} = 2\zeta(k). \]

So here the function does not vanish at 0.

**Definition 5.2.6** Cusp forms. A cusp form is a modular form that vanishes at all cusps.

Given a cusp it will be stabilised by some

\[ \begin{pmatrix} 1 & h \\ 0 & 1 \end{pmatrix} \]

call the smallest such \( h \) for a given cusp the **width** of the cusp.

**Example 5.2.7** Let’s find the width of a cusp in \( \Gamma_0(pq) \) we have

\[ \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} \]

so the width of \( \infty \) is 1.

What about \( \alpha = 1/p \)?

1. Find an element \( \gamma \in \text{SL}_2(\mathbb{Z}) \) s.t. \( \gamma(\infty) = \alpha \).
2. Compute

\[ \delta(x) = \gamma \begin{pmatrix} 1 & x \\ 0 & 1 \end{pmatrix} \gamma^{-1} \]

3. Find the smallest \( x \) such that \( \delta(x) = \Gamma_0(pq) \)
\[ \gamma = \begin{pmatrix} 1 & 0 \\ p & 1 \end{pmatrix}, \quad \gamma(\infty) = \frac{1}{p} \]

\[
\begin{pmatrix} 1 & 0 \\ p & 1 \end{pmatrix} \begin{pmatrix} 1 & x \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ -p & 1 \end{pmatrix} = \begin{pmatrix} 1 - px & x \\ -p^2 & px + 1 \end{pmatrix}
\]

\[ \square \]

**Example 5.2.8 A cusp form.** Let \( \Delta(\tau) = g_2(\tau)^3 - 27g_3(\tau)^2 \), \( g_2(\tau) = 60G_4(\tau) \), \( g_3(\tau) = 140G_6(\tau) \) \( \Delta(\tau) \) has weight 12 for \( \text{SL}_2(\mathbb{Z}) \). This vanishes at \( \infty \) because

\[
\zeta(4) = \frac{\pi^4}{90}
\]

\[
\zeta(6) = \frac{\pi^6}{945}
\]

also

\[
j(z) = \frac{g_2(\tau)^3}{\Delta(\tau)}
\]

so \( \Delta(\tau) \) vanishes at \( \infty \) because \( g_2(\tau) \) doesn’t and \( j(z) \) has a simple pole at \( \infty \).

\[ \square \]

\( M_k(\Gamma) \) as the space of modular forms of weight \( k \) for \( \Gamma \) is a \( C \)-v.s. \( S_k(\Gamma) \) as the space of cusp forms of weight \( k \) for \( \Gamma \) is a \( C \)-v.s.

**Theorem 5.2.9** \( M_k(\Gamma) \) and \( S_k(\Gamma) \) are finite dimensional

\[
\dim(M_k(\Gamma)) = \begin{cases} 
0 & \text{if } k \leq -1 \\
1 & \text{if } k = 0 \\
(k - 1)(g - 1) + v_\infty \frac{k}{2} + \sum_p \left[ \frac{k}{2}(1 - \frac{1}{p^2}) \right] & \text{if } k \geq 2
\end{cases}
\]

where \( g \) is the genus of \( X(\Gamma) \) \( v_\infty \) is the number of inequivalent cusps \( P \) are the elliptic points \([·]\) is the integer part

\[
\dim(S_k(\Gamma)) = g(X(\Gamma))
\]

**Proposition 5.2.10** If \( f \in S_2(\Gamma) \) then \( f(z)\,dz \) is a holomorphic differential.

Given an elliptic curve

\[
E/\mathbb{C} = \mathbb{C}/\Lambda
\]

\[
E \to E'
\]

\[
\mathbb{C}/\Lambda \to \mathbb{C}/\Lambda',
\]

studying degree \( n \) isogenies, is like studying index \( n \) sublattices

**Definition 5.2.11 Hecke operators.** \( n \geq 1 \) then \( T(n) \) is the \( n \)th Hecke operator acting on

\[ \text{Div}(\mathcal{L}) \]

by

\[
T(n)\Lambda = \sum_{\Lambda' \in \Lambda, [\Lambda:\Lambda'] = n} (\Lambda')
\]

\[ \diamond \]
**Definition 5.2.12** Let $\lambda \in \mathbb{C}^\times$ the homothety operator $R_\lambda$ is $R_\lambda \Lambda = \lambda \Lambda$.

**Theorem 5.2.13**

1. $R_\lambda R_\mu = R_{\lambda \mu}$

2. $R_\lambda T(n) = T(n)R_\lambda$

3. $T(nm) = T(n)T(m)$, $\gcd(n, m) = 1$

4. $T(p^e)T(p) = T(p^{e+1}) + pT(p^{e-1})R_p$

**Proof.** Of 4.

$\Lambda \in \mathcal{L}$ for $\Lambda' \subseteq \Lambda$ index $p^{e+1}$ have

$$a(\Lambda') = \#\{\Gamma : \Lambda' \subseteq \Lambda \subseteq \Lambda p\}$$

$$b(\Lambda') = 1 \text{ if } \Lambda' \subseteq p\Lambda$$

now

$$T(p^e)T(p)\Lambda = T(p^e) \sum_{\Gamma \subseteq \Lambda} (\Gamma) = \sum_{\Gamma \subseteq \Lambda} \sum_{\Lambda' \subseteq \Lambda p} (\Lambda') = \sum_{\Lambda' \subseteq \Lambda p} a(\Lambda')(\Lambda')$$

$$T(p^{e+1})\Lambda = \sum_{\Lambda' \subseteq p^{e+1} \Lambda} (\Lambda')$$

$$T(p^{e-1})R_p\Lambda = T(p^{e-1})(p\Lambda) = \sum_{\Lambda'' \subseteq p^{e-1} \Lambda} (\Lambda'') = \sum_{\Lambda' \subseteq p^{e+1} \Lambda} b(\Lambda')(\Lambda')$$

Split into cases, do some maths...

Hecke operators on lattices Given $\Lambda' \subseteq \Lambda$ there is an integer matrix of determinant $n$ taking one basis to the other. Have a correspondence

$$\{\alpha \in M_2(\mathbb{Z}) : \det(\alpha) = n\} \leftrightarrow \{\Lambda' : \Lambda' \subseteq \Lambda \}$$

representatives in Hermite normal form

$$S_n = \left\{ \begin{pmatrix} a & b \\ 0 & d \end{pmatrix} : ad = n, a, d > 0, 0 \leq b < d \right\}$$

**Corollary 5.2.14** Let $\Lambda \in \mathcal{L}$, $\Lambda = \mathbb{Z}w_1 + \mathbb{Z}w_2$ then $T(n)$ acts as follows

$$T(n)\Lambda = \sum_{ad=n, a,d > 0, 0 \leq b < d} \mathbb{Z}(aw_1 + bw_2) + \mathbb{Z}d w_2 = \sum_{\alpha \in S_n} \alpha \Lambda$$

**Corollary 5.2.15** For $p$ prime $T(p)$:

$$T(p)\Lambda = \mathbb{Z}pw_1 + \mathbb{Z}w_2 + \sum_{0 \leq b < p} \mathbb{Z}(w_1 + bw_2) + \mathbb{Z}pw_2.$$
This boils down to
\[(T_k(n) f)(\tau) = n^{k-1} \sum_{ad=n, a,d>0, 1 \leq b < d} d^{-k} f \left( \frac{a \tau + b}{d} \right)\]

**Corollary 5.2.16** For \( p \) prime
\[(T_k(p) f)(\tau) = p^{k-1} f(pz) + \frac{1}{p} \sum_{0 \leq b < p} f \left( \frac{z + b}{p} \right).\]

We have an action on Fourier expansions
\[f(\psi) = \sum_{m \in \mathbb{Z}} a_m q^m\]
\[T_k(p) f(\tau) = p^{k-1} \sum_{m \in \mathbb{Z}} a_m q^{pm} + \frac{1}{p} \sum_{b=0}^{p-1} \left( \sum_{m \in \mathbb{Z}} a_m e^{2\pi i m (z+b)/p} \right)\]
\[= p^{k-1} \sum_{m \in \mathbb{Z}} a_m q^{pm} + \frac{1}{p} \sum_{m \in \mathbb{Z}} a_m e^{2\pi i m z/p} \sum_{b=0}^{p-1} \frac{e^{2\pi i mb/p}}{p \text{ if } p|m, \text{ otherwise}}\]
\[= p^{k-1} \sum_{m \in \mathbb{Z}} a_m q^{pm} + \sum_{m \in \mathbb{Z}} a_{pm} q^m\]

**Corollary 5.2.17**
\[a_1(T_p(f)) = a_p(f)\]
If \( f \in S_k(\Gamma_0(1)) \) is an eigenfunction for these operators we can normalise so that \( a_1(f) = 1 \).
\[T(m)T(n) = T(mn)\]
\[a_m a_n = a_{mn}\]
\[a_{pr} = a_p a_{pr-1} + p^{k-1} a_{pr+1}\]

**Definition 5.2.18** **Petersson inner product.** The Petersson inner product of two cusp forms \( f, g \in S_k(SL_2(\mathbb{Z})) \) is defined to be
\[\langle f, g \rangle = \int_D f \overline{g} y^{k-2} \, dx \, dy\]
where \( D \) is a fundamental domain for \( SL_2(\mathbb{Z}) \).

**Proposition 5.2.19** Let \( f, g \in S_k(SL_2(\mathbb{Z})), n \in \mathbb{N} \) then
\[\langle T(n)f, g \rangle = \langle f, T(n)g \rangle.\]

### 5.3 Abelian varieties and Jacobians (Angus)

#### 5.3.1 Background

**Definition 5.3.1** An elliptic curve is any one of the following
1. Smooth projective curve of genus 1 with a marked rational point.
2. A smooth projective curve with a group law
3. if \( k \subseteq \mathbb{C} \) we have
\[
E(\mathbb{C}) = \mathbb{C}/\Lambda
\]
\[
\Lambda = \mathbb{Z}\omega_1 \oplus \mathbb{Z}\omega_2, \ \omega_1/\omega_2 \not\in \mathbb{R}
\]

4. if char \( k \neq 2, 3 \) A smooth projective curve specified by
\[
y^2 = x^3 + ax + b.
\]

Aash showed that 1 implies 4 and 3 implies 1.

One can view the group law on \( E \) either via the chord-tangent method (Bezout’s theorem). Or via the isomorphism
\[
E \rightarrow \text{Pic}^0(E)
\]
\[
P \mapsto [P] - [0].
\]

**Definition 5.3.2** An abelian variety is a proper irreducible variety with a group law given by regular functions.

**Remark 5.3.3**

1. In this definition proper is equivalent to projective.

2. The rigidity theorem tells us:
   
   (a) Any morphism of abelian varieties that preserves the identity is a homomorphism.

   (b) Abelian varieties are abelian

### 5.3.2 Abelian varieties over \( \mathbb{C} \)

**Proposition 5.3.4** Let \( A/k \subseteq \mathbb{C} \) then
\[
A(\mathbb{C}) = \mathbb{C}^g/\Lambda
\]
where \( g = \text{dim } A \) and \( \Lambda \subseteq \mathbb{C}^g \) is a rank \( 2g \) lattice.

**Proof.** The lie algebra \( \text{Lie}(A(\mathbb{C})) \) is a complex vector space of dimension \( g \). We have the exponential
\[
\exp : \text{Lie}(A(\mathbb{C})) \rightarrow A(\mathbb{C})
\]
which is surjective onto the connected component of the identity, and locally at 0 a diffeomorphism. So \( \exp \) surjects. Since its locally isomorphic at 0 we have \( \ker(\exp) \) discrete and hence a lattice. A proper means \( A(\mathbb{C}) \) is compact so
\[
\text{rank } \ker(\exp) = 2g.
\]

We have a map
\[
\{\text{AVs}/\mathbb{C}\} \rightarrow \{\text{complex tori}\}
\]
but this is not surjective. Which lattices give AVs?

**Definition 5.3.5** Hermitian forms. Let \( V \) be a \( \mathbb{C} \)-vector space and \( \Lambda \subseteq V \) be a full lattice. A **Hermitian form** on \( V \) is a function
\[
H : V \times V \rightarrow \mathbb{C}
\]
which is \( \mathbb{C} \)-linear in the first component, \( \mathbb{C} \)-antilinear in the second (i.e. a
sesquilinear form). And satisfies

\[ H(u, v) = H(v, u) \]

A Riemann form on \((V, \Lambda)\) is a positive definite Hermitian form on \(V\) s.t. \(\text{im}(H|_V) : \Lambda \to \mathbb{Z}\).

**Proposition 5.3.6** We have a bijection

\[
\{\text{AVs}/\mathbb{C}\} \leftrightarrow \{(V, \Lambda) \text{ s.t. there is a Riemann form on } (V, \Lambda)\}.
\]

**Proof.** Swinnerton-Dyer analytic theory of AVs ch.2. ■

**Example 5.3.7** For an elliptic curve \(E(\mathbb{C}) = \mathbb{C}/\mathbb{Z}\omega_1 + \mathbb{Z}\omega_2\)

\[ H(u, v) = \frac{u \bar{v}}{\text{im}(\omega_1 \bar{\omega}_2)}. \]

\[ \square \]

### 5.3.3 Jacobian varieties

**Definition 5.3.8** Given \(X\) a curve

\[ \text{Pic}^0(X) = \text{Div}^0(X)/\{(f) : f \in K(X)\} \]

this is some abelian group.

**Theorem 5.3.9** Let \(X\) be a genus \(g\) curve \(/k\). Then there exists an abelian variety \(\text{Jac}(X)/k\) of \(\text{dim} = g\) s.t.

\[ \text{Jac}(X)(L) = \text{Pic}^0(X \otimes L) \]

**Remark 5.3.10** This is false as stated unless \(X(k) \neq \emptyset\).

**Proof.** Idea: Pick \(P_0 \in X(k)\) we have a bijection

\[ \text{Div}^0(X) \to \text{Div}^r(X) \]

\[ D \mapsto D + r[P_0] \]

we have a map

\[ X^r \to X^r/S_r = X^{(r)} \to \text{Div}^r(X) \]

we can construct \(\text{Jac}(X)\) as a quotient of \(X^{(r)}\) full details Milne AVs ch. 2. ■

**Jacobian over \(\mathbb{C}\).** Given \(X\) a compact Riemann surface of genus \(g\) then

\[ H^0(X, \Omega^1_X) \approx \mathbb{C}^g \]

one might wish to consider, for \(P, Q \in X, \omega \in H^0(X, \Omega^1_X)\)

\[ \int_P^Q \omega \]

this is not well defined as there are choices of path \(P \to Q\).

\[ H_1(X, \mathbb{Z}) = \mathbb{Z}^{2g} \]

have a map

\[ H_1(X, \mathbb{Z}) \to H^0(X, \Omega^1_X)^\vee \]
\[ \gamma \mapsto (\omega \mapsto \int_{\gamma} \omega) \]

Let

\[ J(X) = H^0(X, \Omega^1_X)^{\dagger} / H_1(X, \mathbb{Z}) \]

**Theorem 5.3.11** \(J(X)\) is the \(\mathbb{C}\) points of an abelian variety over \(\mathbb{C}\). Further the map

\[ \text{Pic}^0(X) \to J(X) \]

\[ [P] - [Q] \mapsto (\omega \mapsto \int_{Q}^P \omega) \]

is an isomorphism of abelian groups.

**Proof.** For the first claim we need a Riemann form on

\( (H^0(X, \Omega^1_X)^{\dagger}, H_1(X, \mathbb{Z})) \)

we have

\[ H_1(X, \mathbb{Z}) \times H_1(X, \mathbb{Z}) \to \mathbb{Z} \]

\( (\gamma_1, \gamma_2) \mapsto -\left( \gamma_1 \cap \gamma_2 \right) \).

\[ \blacksquare \]

**Remark 5.3.12** In this case we see

\[ \text{Lie}(\text{Jac}(X)) = H^0(X, \Omega^1_X) \]

this is true in general.

### 5.3.4 Some constructions/properties of AVs

Let \(A, B\) be AVs/\(k\). Any identity preserving morphism \(\phi: A \to B\) is a homomorphism. Such a homomorphism is called an isogeny if it surjective with finite kernel. i.e. \([n]: A \to A\) is an isogeny and for \(\text{char}(k) \nmid n\).

\[ A[n] \cong (\mathbb{Z}/n)^{2g} \]

then we have the Tate module for \(l\) prime

\[ T_lA = \varprojlim_n A[l^n] \cong \mathbb{Z}_l^{2g} \]

in fact

\[ H^1_{\text{et}}(A, \mathbb{Z}_l) \cong T_lA^{\dagger} \]

we can also consider \(\text{Pic}^0(A)\). There exists an abelian variety

\[ \hat{A}/l \]

s.t.

\[ \hat{A}(L) = \text{Pic}^0(A \otimes L) \]

this is called the dual abelian variety. So earlier we saw \(\hat{E} \cong E\). in general \(\hat{A} \neq A\).

However for an ample divisor \(D\) we get an isog

\[ \phi_D: A \to \hat{A} \]

\[ P \mapsto t^*_pD - D \]
an isogeny \( \phi: A \to \hat{A} \) is a polarization if

\[
\phi = \phi_D/\hat{k}
\]

over \( \mathbb{C} \) a polarization is equivalent to a choice of Riemann form. A principal polarization is a polarization which is an isomorphism. e.g.

\[
\phi_{[0]}: E \to \hat{E} \\
P \mapsto [P] - [0]
\]

**Remark 5.3.13** Jacobian varieties always admit principal polarizations. On \( T_1A \) we have a Weil pairing

\[
T_1A \times T_1A^\vee \to \mathbb{Z}_l
\]

**Maps between Jacobians.** Let \( X, Y/k \) be curves and \( f: X \to Y \) a morphism.

**Definition 5.3.14** We have a pushforward map

\[
f_*: \text{Pic}^0(X) \to \text{Pic}^0(Y) \\
\sum n_x[x] \mapsto \sum n_x[f(x)]
\]

if \( f \) is finite then we have a pullback

\[
f^*: \text{Pic}^0(Y) \to \text{Pic}^0(X) \\
\sum n_y[y] \mapsto \sum n_y[f^{-1}(y)]
\]

(with multiplicity).

We want further maps between Jacobians

**Definition 5.3.15** A correspondence between \( X, Y \) is a curve \( Z \) and a pair of finite morphisms.

\[
X \leftarrow Z \to Y
\]

then we get induced maps

\[
T_* = g_*f^*: \text{Pic}^0(X) \to \text{Pic}^0(Y) \\
T^* = f_*g^*: \text{Pic}^0(Y) \to \text{Pic}^0(X)
\]

**Modular Jacobians and Hecke Correspondences.** Consider \( p \nmid N \) we have

\[
X_0(N) = \{(E, C_N): E \text{ e.c. }, C_N \text{ cyclic sub order } N\}
\]

\[
X_0(pN) = \{(E, C_{pN})\} = \{(E, C_N, C_p)\}
\]

so we have

**Definition 5.3.16** the Hecke correspondence \( T_p \) on \( X_0(N) \) is

\[
X_0(N) \leftrightarrow X_0(pN) \to X_0(N) \\
(E, C_N) \leftrightarrow (E, C_N, C_p) \to (E/C_p, C_p + C_N).
\]
We have the modular jacobian $J_0(N)$ and the induced map

$$T_p: J_0(N) \to J_0(N)$$

$$[E] \mapsto \sum_{C_p \in E} [E/C_p]$$

One can consider $J_0(N)_{\mathbb{F}_p}$

**Theorem 5.3.17 Eichler-Shimura.** $T_{p^*} = \text{Frob}_p + p \text{Frob}_p^{-1} \in \text{End}(J_0(N)_{\mathbb{F}_p})$.

### 5.4 Ricky Show

#### 5.4.1 Moduli of PPAVs

Recall if $A/\mathbb{C}$ is an abelian variety, then

$$A = A(\mathbb{C}) = \mathbb{C}^g/\Lambda, \ g = \dim(A)$$

$$\Lambda \cong H_1(A, \mathbb{Z})$$

Also a polarization $\lambda: A \to A^\vee$ is equivalent to choosing a Riemann form

$$E: \Lambda \times \Lambda \to \mathbb{Z}$$

s.t.

1. $E$ is bilinear alternating
2. $E_{\mathbb{R}}: V \times V \to \mathbb{R}$ has $E_{\mathbb{R}}(iv, iw) = E_{\mathbb{R}}(v, w)$.
3. 

$$H(v, w) = E_{\mathbb{R}}(iv, w) + iE_{\mathbb{R}}(v, w)$$

is a positive definite Hermitian form on $V$.

A principal polarization corresponds to $E$ being a perfect pairing.

**Definition 5.4.1** A PPAV (principally polarized abelian variety) is a pair $(A, \lambda)$.

If $(\mathbb{Z}^{2g}, \Psi)$ is the standard $2g$-dim symplectic form $\Psi$ then by linear algebra there is a symplectic isomorphism

$$\alpha: \mathbb{Z}^{2g} \to \Lambda$$

with $\Psi(v, w) = E(\alpha(v), \alpha(w))$.

Recall the standard $\Psi$ is

$$\Psi(v, w) = v^T J w, \ J = \begin{pmatrix} 0 & I_g \\ -I_g & 0 \end{pmatrix}$$

**Definition 5.4.2** The Siegel upper half space is

$$\mathcal{H}_g = \{Z = X + iY \in M_g(\mathbb{C}) : Z^T = Z; \ X, Y \in M_g(\mathbb{R}); \ Y > 0\}$$

i.e. $Y$ is pos. def.

Check: $\mathcal{H}_1$ is the usual upper half plane.
**Proposition 5.4.3** \( \mathcal{H}_g \cong \text{Sp}_{2g}(R)/U(g) \) where \( \text{Sp}_{2g}(R) = \{ M \in \text{GL}_{2g}(R) : M^T M = I \} \)

\( U(g) = \text{O}(2g) \cap \text{Sp}_{2g}(R) \cap \text{GL}(C) \).

**Proof.** (Sketch) First one can show that \( \text{Sp}_{2g}(R) \) acts transitively on \( \mathcal{H}_g \) via linear fractional transformations:

\[
M = \begin{pmatrix} A & B \\ C & D \end{pmatrix} \in \text{Sp}_{2g}(R), \ Z \in \mathcal{H}_g
\]

\( M \cdot Z = (AZ + B)(CZ + D)^{-1} \in \mathcal{H}_g \)

second one computes \( \text{Stab} J = U(g) \)

For \( g = 1 \), \( \text{Sp}_2(R) = \text{SL}_2(R) \) acts transitively on \( \mathcal{H}_1 \), \( \text{Stab}(i) = \text{SO}(2) = U(1) \).

\[
\begin{pmatrix} \cos \theta & \sin \theta \\ -\sin \theta & \cos \theta \end{pmatrix} i = i
\]

and if

\[
\begin{pmatrix} a & b \\ c & d \end{pmatrix} i = i
\]

then \( ai + b = -c + di \) so \( M = \begin{pmatrix} a & b \\ -b & a \end{pmatrix} \in \text{SO}(2) \). \( \blacksquare \)

**Proposition 5.4.4** There is a natural bijection between

\( \{(A, \lambda, \alpha) : (A, \lambda) = \text{PPAV}, \ \alpha : \mathbb{Z}^{2g} \rightarrow \Lambda \} \rightarrow \mathcal{H}_g \)

this induces a bijection

\( \{(A, \lambda) \} \rightarrow \text{Sp}_{2g}(\mathbb{Z}) \backslash \mathcal{H}_g = \text{Sp}_{2g}(\mathbb{Z}) \backslash \text{Sp}_{2g}(R)/U(g) \).

**Proof.** We will construct a map

\( \{(A, \lambda, \alpha) \} \rightarrow \text{Sp}_{2g}(R)/U(g) \)

first we construct a bijection between

\( \{(A, \lambda, \alpha) \} \)

and some linear data on a fixed space, so given \( (A, \lambda, \alpha) \) use \( \alpha \) to identify

\( \alpha : \mathbb{Z}^{2g} \rightarrow \Lambda = H_1(A, \mathbb{Z}) \)

then tensor with \( R \) to get

\( \alpha_R : \mathbb{R}^{2g} \rightarrow \Lambda \otimes R \cong \text{Lie}(A)(= C^g) \)

the action of \( i \) on the right induces \( J \) on the left with \( J^2 = -I \).

From \( E_R(iv, iv) = E_R(v, w) \) we get \( J \) symplectic

\( \Psi_R(Jv, Jw) = \Psi_R(v, w) \)

from \( E_R(iv, v) > 0 \) we get \( J \) is positive

\( \Psi_R(Jv, v) > 0 \)

conversely given \( J \) symplectic positive \( J^2 = -I \) on \( \mathbb{R}^{2g} \) we can construct \( (A, \lambda) = (V/\mathbb{Z}^{2g}, E) \) This comes with an \( \alpha \) for free since \( H_1(A, \mathbb{Z}) \cong \mathbb{Z}^{2g} \).
Suppose \( J \) and \( J_0 \) are two complex structures, symplectic positive matrices on \( \mathbb{R}^{2g} \). Then a lemma from linear algebra tells us that there exists a \( S \in \text{Sp}_{2g}(\mathbb{R}) \) s.t. \( J_0 = JS^{-1} \). We see that this \( S \) is well defined up to an element of \( G = Z(j) \cap \text{Sp}_{2g}(\mathbb{R}) \). But if \( \gamma \in G \) then \( \gamma \) preserves the associated \( \mathbb{C} \)-str. on \( \mathbb{R}^{2g} \). Then since \( \gamma \) is symplectic, it preserves

\[
H(v, w) = E_R(i\nu, w) + iE_R(v, w)
\]

implies

\[
\gamma \in U(g).
\]

5.4.2 Hodge structures

Let \( M \) be a \( C^\infty \) compact \( \mathbb{R} \)-manifold. Then \( H^{i}_{\text{sing}}(M, \mathbb{R}) \equiv H^{i}_{\text{dR}}(M) \). What about for compact \( \mathbb{C} \)-manifolds \( X \)? For \( M \) have \( H^{i}_{\text{dR}}(M) = H^{i}(\Omega^{\bullet}(M)) \). This won’t give de Rham isomorphism for \( X \):

\[
H^{i}_{\text{sing}}(X)
\]

supported up to \( i = 2d \) with \( d = \text{dim}_{\mathbb{C}}(X) \). but \( H^{i}(\Omega^{\bullet}_{\text{hol}}(\mathbb{C})) \) is supported up to \( i = d \).

For \( M \)

\[
0 \to \mathbb{R} \to \Omega^{0} \to \Omega^{1} \to \cdots \to \Omega^{d} \to 0
\]

is a resolution of \( R \) by acyclic sheaves, by the existence of \( \mathbb{C}^\infty \) bump functions.

\[
H^{i}_{\text{dR}}(M) \equiv H^{i}(M, \mathbb{R}) \equiv H^{i}_{\text{sing}}(M, \mathbb{R}).
\]

For \( X \) this doesn’t work with \( \Omega^{\bullet}_{\text{hol}} \) as there are no holomorphic bump functions.

\[
0 \to \mathbb{C} \to \Omega^{0}_{\text{hol}} \to \Omega^{1}_{\text{hol}} \to \cdots \to \Omega^{\bullet}_{\text{hol}} \to 0
\]

is still a resolution but not acyclic. Instead we use hypercohomology which takes as input any resolution and outputs a cohomology group. This has the property that

\[
H^{i}(X, \mathbb{C}) \equiv H^{i}(\Omega^{\bullet}_{X})
\]

so we define \( H^{i}_{\text{dR}}(X) = H^{i}(\Omega^{\bullet}_{X}) \), so that

\[
H^{i}_{\text{dR}}(X) \equiv H^{i}(X, \mathbb{C}) \equiv H^{i}_{\text{sing}}(X, \mathbb{C})
\]

On \( X \) we have the sheaf of \((p, q)\) forms \( \Omega^{p,q} \). These are locally given by

\[
\sum_{|l|=p,|\ell|=q} f_{l,\ell} \, dz_l \, d\bar{z}_\ell.
\]

We have

\[
\bar{\partial} : \Omega^{p,q} \to \Omega^{p,q+1}
\]

satisfying \( \bar{\partial}^2 = 0 \). So we can define \( H^{p,q}(X) = \ker \bar{\partial} / \text{im} \bar{\partial} \) (Dolbeaut cohomology).

Theorem 5.4.5 Hodge decomposition. For a compact Kahler manifold (e.g. \( X \) a
We have
\[ H^0_{\text{dR}}(X) \cong \bigoplus_{p+q=n} H^{p,q}(X). \]

**Remark 5.4.6**
\[ H^{p,q}(X) \cong H^q(X, \Omega^p) \]
using \( \partial \) Poincaré lemma.

**Example 5.4.7** E/C elliptic curve.
\[
\begin{align*}
H^0_{\text{dR}} &= H^{0,0} \\
H^1_{\text{dR}} &= H^{1,0} \oplus H^{0,1} \\
H^2_{\text{dR}} &= H^{2,0} \oplus H^{1,1} \oplus H^{0,2}
\end{align*}
\]
outer terms 0, diamond is 1, 1, 1, 1.

**Definition 5.4.8** Hodge structures. A Hodge structure on \( V/\mathbb{R} \) is a \( \mathbb{Z} \)-bigrading on \( V_{\mathbb{C}} = V \otimes \mathbb{C} \) such that
\[
\overline{V}^{p,q} = V^{q,p}
\]
its of Hodge type \( S \subseteq \mathbb{Z}^2 \) if \( V^{p,q} \neq 0 \iff (p, q) \in S \).

**Example 5.4.9** the Hodge decomposition gives a hodge structure on \( H^n_{\text{sing}}(X, \mathbb{R}) \).

If \( V \) has a hodge structure of weight \( n \) (i.e. \( V^{p,q} \neq 0 \iff p, q = n \)). Then we can recover the hodge structure from the associated hodge filtration
\[
\text{Fil}^p V_{\mathbb{C}} = \bigoplus_{p' \geq p} V^{p',q}
\]

**Example 5.4.10**
\[
\begin{align*}
\text{Fil}^0(H^1(E)) &= H^{1,0} \oplus H^{0,1} \\
\text{Fil}^1(H^1(E)) &= H^{1,0} \\
\text{Fil}^2(H^1(E)) &= 0
\end{align*}
\]

**Exercise 5.4.11**
\[ V^{p,q} = \text{Fil}^p V \cap \overline{\text{Fil}^q V} \]
in weight \( n \).

**Alternative definition.**
\[
S = \text{Res}_R G_m
\]
\[
S(A) = \{(a, b) \in A^2 : a^2 + b^2 \neq 0\}
\]
\[
S(\mathbb{R}) = \mathbb{C}^\times
\]

**Proposition 5.4.12** There is a natural bijection between morphisms of algebraic groups
\[ S \rightarrow \text{GL}(V) \]
and Hodge structures on \( V \).
Hence for any lie group \( G \) we can define a hodge structure on \( G \) as a morphism of algebraic groups
\[
S \to G
\]
If \( G \to \text{GL}(V) \) is a faithful rep this induces a hodge structure on \( V \).

**Definition 5.4.13** A polarization of a HS \( h: S \to \text{GL}(v) \) is an alternating bilinear form
\[
\Psi: V \times V \to \mathbb{R}
\]
with
1. \( \Psi(fv, jw) = \Psi(v, w) \) for \( f = h(i) \)
2. \( \Psi(v, jw) \) is pos. def.

\( \diamond \)

### 5.5 Variations of Hodge Structures (Sachi)

#### 5.5.1 Review of Hodge Theory

\( X \) complex manifold \( X \subseteq \mathbb{P}^N \) which is \( m \)-dimensional. For each \( n \) associate to \( X \)
\[
H_Z = H^n_{\text{sing}}(X, \mathbb{Z})/\text{tors}
\]
\[
H_C = H_Z \otimes \mathbb{C} = H^n_{\text{dR}}(X)
\]
we have a bilinear pairing
\[
Q: H_Z \times H_Z \to \mathbb{Z}
\]
\[
Q(\alpha, \beta) = \int_X \alpha \cup \beta \cup \omega^{m-n}
\]
where \( \omega \) is a generator of \( H^2(\mathbb{P}^N, \mathbb{Z}) \) restricted to \( X \). This gives us the set-up of \( X \) as a differentiable manifold. Now say something about complex structure. We have a decomposition of differential forms on \( X \)
\[
A^n(X) = \bigoplus_{p+q=n} A^{p,q}
\]
degree \( n \) forms decomposing as a combination of type \( p, q \) forms.

Hodge theorem descends to a decomposition on cohomology
\[
H^n_{\text{dR}}(X) = \bigoplus_{p+q=n} H^{p,q}
\]
\[
H^{p,q} = H^{q,p}
\]
\[
Q(H^{p,q}, H^{p',q'}) = 0
\]
unless \( p + p' = q + q' = n \).

A hodge structure of weight \( n \) is the data \( (H_Z, Q) \) satisfying the Hodge decomposition, Bilinearity

Questions:
1. To what extent does the HS of \( X \) determine \( X \)? (Torelli problem)
2. To what extent can we read off the geometric data of \( X \) from its Hodge structure.
5.5.2 Variations of Hodge structures:
Let $Y \subseteq X$ be codimension $k$, this gives a class in
$H^{k,k}(X) \subseteq H^{2k}(X, \mathbb{C})$
what about the converse?
For each cohomology class $\gamma$ in $H^{2k}(X, \mathbb{C})$ is $\gamma$ a rational linear combination of classes of subvarieties. (Hodge conjecture).

5.5.2.1 Hodge theory for curves
$(H_Z, \mathbb{Q}), H^{1,0} \oplus H^{0,1}$ have the period matrix
$H^{0,1}/\Lambda \cong \text{Jac}(\mathbb{C})$
$y^2 = x(x-1)(x-\lambda)$
$\lambda \in \mathbb{P}^1 - \{0, 1, \infty\}$
each $E_\lambda \leftrightarrow H^{1,0} \oplus H^{0,1}$ so can ask as $\lambda$ varies we can ask how $H^{1,0}$ is situated inside of $H^{1,0} \oplus H^{0,1}$.

$\omega = \frac{dx}{y} \in H^0(X, \Omega_X)$

pairing with $H^1(X)$
$\int_\gamma \omega$.

For $B$ a variety $\{X_b\}$ are varieties with Hodge structures for each $b \in B$.
Locally we can identify $H_Z = H^n(X_b, \mathbb{Z})/\text{tors}$
and $H_{\mathbb{C}}$ with that of $X_{b_0}$.
Then consider $H^{u-k,k}(X_b)$
or the associated
$F^k = \bigoplus_{l=0}^k H^{u-l,l}(X_b)$
subspaces of $H_{\mathbb{C}}$.

Question: What is a moduli space of linear subspaces?
Answer: The Grassmanian!

$\text{Gr}(k, V)$
of $k$-dimensional subspaces of a fixed vector space $V$. What is the tangent space to the Grassmanian at a point $W \subseteq V$?
$\text{Hom}(W, V/W)$
if we take the complementary subspace $W \oplus C = V$ given another subspace $W' \cap C = \{0\}$

have $\pi_W, \pi_C$
$\text{Gr}(k, V) = \{\text{all } W'\}$
$\cong \text{Hom}(W, C)$
by $\pi_C \circ (\pi_W|_{W'})^{-1}$.
Fact 5.5.1
1. \( \phi: B \to \text{Gr} \) mapping \( b \mapsto F^k(X_b) \subseteq H_C \) is holomorphic.

2. In terms of identifying the tangent space of the grassmanian to the hom set, the image under
\[
d\phi_k = \delta_k
\]
of any tangent vector of \( B \) at \( b_0 \) carries \( F^k \) to \( F^{k+1}/F^k \) so we have maps
\[
\delta_k: T_{b_0}B \to \text{Hom}(H^{n-k,k}(X), H^{n-k-1,k+1}(X))
\]
satisfying
\[
\delta_{k+1}(V) \circ \delta_k(W) = \delta_{k+1}(W) \circ \delta_k(W)
\]
for all \( v, w \in T \).

Since \( F^k(X_b) \) satisfy
\[
Q(F^k, F^{n-k-1}) = 0
\]
for all \( b \).

\[
Q(\delta_{\alpha}(v)(\alpha), \beta) + Q(\alpha, \delta_{n-k-1}(v)(\beta)) = 0
\]
for all \( \alpha \in H^{n-k,k}(X), \beta \in H^{k+1,n-k-1}(X) \) for \( v \in T \)

Definition 5.5.2 Infinitesimal variation of Hodge structures. An infinitesimal variation of Hodge structures is
\[
(H_Z, Q, H^{p,q}, T, \delta_q: T \to \text{Hom}(H^{p,q}, H^{p-1,q+1}))
\]

Two observations:

Remark 5.5.3 Variations of hodge structures are often computable, e.g. for hypersurfaces in \( \mathbb{P}^N \).

\[
X \subseteq \mathbb{P}^{n+1}
\]

let \( X = \{ f = 0 \} \) of deg \( d \).

Lefschetz implies the only interesting cohomology is in the middle dimension.

\[
H^n(X), \ H^{n,0}(X)
\]
Poincaré residues of \( n + 1 \) forms of \( \mathbb{P}^{n+1} \) with poles along \( X \)
\[
\frac{\text{Res}_{\omega,g(z_0, \ldots, z_{n+1})}}{f} = \frac{g\hat{\Omega}}{\sum \frac{\partial f}{\partial z_i}}.
\]

\[
\text{C}[z_0, \ldots, z_{n+1}]/\text{Jacobian ideal}
\]

graded parts \( H^{p,q}(X) \)

Problem 5.5.4 Identify \( H_Z \) inside of \( H^n \)

Solution: VHS \( \delta_k \) maps turn out to be polynomial multiplication \( d \geq n + 1 \).

Theorem 5.5.5 Noether-Lefschetz. A surface \( S \subseteq \mathbb{P}^4 \) of degree \( d \geq 4 \) having general moduli contains no curves other than complete intersections \( S \cap T \) with other surfaces \( T \).
5.6 Moduli of linearized $C$-structures (RICKY)

5.6.1 Motivation: Period morphisms

Recall for $A$ a polarized $AV$ we get a lattice $H_1(A, Z)$ with some structure. To keep track of the $C$-structure we record the Hodge structure induced on $H_1(A, R)$ via the Hodge decomposition theorem. If we want to say construct a moduli space of Elliptic Curves we might try to create a moduli space of $C$-structures on a fixed torus $T$.

The linearized version of this is to fix $H_1(T, R)$ and consider possible Hodge structures on it.

Example 5.6.1

$E_\lambda: y^2 = x(x - 1)(x - \lambda)$

$E \to S = \mathbb{P}^1 \setminus \{0, 1, \infty\}$

then we can identify $V_\lambda = H^1_{\text{sing}}(E_\lambda, R)$ for nearby $\lambda \in S$. Then the Hodge structure looks like:

$$F^1V_{\lambda,C} = \langle \frac{dx}{y} \rangle \hookrightarrow V_{\lambda,C}$$

this induces a period map

$$S \supset U \to \mathbb{P}^1$$

sending $s \mapsto F^1V_{s,C}$. □

Today generalise the role of $\mathbb{P}^1$ in this.

5.6.2 Moduli of Hodge structures

Recall: a Hodge structure on a real vector space $V$ is equivalent to a morphism $h: S \to \text{GL}(V)$ where $S = \text{Res}_{\mathbb{R}}^C G_m$. Given $h$ let

$$V^{p,q} = \{ v \in V_C : h(z)v = z^{-p}z^{-q}v \}$$

(the characters of $S$ are of the form $\chi_{p,q} = z^{-p}z^{-q}$ for $(p,q) \in \mathbb{Z}^2$. So a general Hodge structure on a Lie group $G$ is defined to be a map $S \to G$.

Lemma 5.6.2 The combinatorial data of two Hodge structures are the same iff they are conjugate (i.e. the maps $S \to \text{GL}(V)$ are conjugate).

Proof. If $h$ and $h'$ are conjugate by $g$ then conjugation by $g$ takes $V^{p,q}$ of one into the other (b/c it preserves the character spaces of $S$). Conversely if $\{V^{p,q}_1, V^{p,q}_2\}$ are two HS with the same combinatorial data then we can take $g: V_C \to V_C$. Taking $V^{p,q}_1 \cong V^{p,q}_2$ and satisfying $g(\bar{v}) = \bar{g}(v)$ (using Hodge symmetry) since $g$ commutes with $\bar{\cdot}$, it descends to a map on $V$. ■

Let $X$ be a conjugacy class of morphisms $h: S \to G$.

Impose the condition that:

$$h(R^\times) \text{ lies in the center of } G(R)/(h)$$

(If the HS on $V$ is of weight $k$ then $h(t) = t^kI$, the converse is also true.)

$G$ acts transitively on $X$ (via conjugation). So

$$X = G/K$$

for $K = \text{Stab}(h)$ for some $h$ in $X$. This gives $X$ the structure of a $C^\infty$-manifold.
The C-structure on $X$. We give $T_hX = \text{Lie} G/\text{Lie} K$ a C-v.s. structure let $\psi_h(x) = gxg^{-1}$ gives $G \to \text{Aut}(G)$

and its derivative is the adjoint map $\text{ad}$. If we compose with $h: S \to G$ we get a hodge structure on $L = \text{Lie} G$.

As $h(R^\times)$ is in the center of $G(R)$, have $\text{ad} h(R^\times)$ is the identity on $L$. Hence the hodge structure on $L$ is of weight 0. By above remark.

Let $L^{0,0} = L^0_C \cap L$ be the real $(0,0)$ part of the HS on $L$.

Lemma 5.6.3

$L^{0,0} = \text{Lie} K$

Proof. By the definition of $K$, $\psi_h(k) = k$ for all $k \in K$. Differentiating gives

$$ (\text{ad} h)(v) = v $$

for all $v \in \text{Lie} K$ So Lie $K \subseteq L^{0,0}$. Conversely if $v \in L^{0,0}$ then $(\text{ad} h)(v) = v$

implies

$$ (\text{ad} h)(\exp v) = \exp v $$

so $\exp v \in K$ i.e. $v \in \text{Lie} K$.

Lemma 5.6.4 The inclusion $L \hookrightarrow L_C$ induces an isomorphism of R-v.s.

$$ L/L^{0,0} \cong L_C/F^0 L_C. $$

Proof. see notes.

These lemmas combined give $T_hX$ a C-structure.

To get a C-manifold structure on $X$ we embed $X$ into a C manifold in a way that respects the C-structures on the tangent spaces.

Pick a faithful representation $G \hookrightarrow \text{GL}(V)$. Then $h \in X$ we get a Hodge structure on $V$ via

$$ S \xrightarrow{h} G \xrightarrow{\rho} \text{GL}(V) $$

all other $h' \in X$ have the same combinatorial data.

Let $F$ be the flag variety parameterises filtrations of the type associated to $h \in X$.

To be safe assume $V$ of weight $k$.

We have an injective map

$$ X \hookrightarrow \phi F $$

this induces a complex structure on $X$, see notes for deets.

5.6.3 Geometric conditions and chill (on VHS)

Recall that a VHS parameterised by a space $S$ must satisfy “Griffiths transversality”, this translates to the condition

Theorem 5.6.5 A VHS on $V$ satisfies Griffiths transversality iff

$$ \text{the HS on } L = \text{Lie}(G) \text{ of type } \{(-1,1), (0,0), (1,-1)\}. $$

Background on Cartan involutions. Let $G$ be a real algebraic group with involution $\sigma$. Then a real form of $G$ associated to $\sigma$ is

$$ G^\sigma(A) = \{g \in G(A \otimes \mathbb{C}) : \sigma(g) = \tilde{g}\} $$

for all $\mathbb{R}$-algebras $A$. 

Example 5.6.6 \(G = \text{GL}_n, \sigma(g) = (g^\perp)^{-1}\) then
\[G^\sigma = U(n)\]
observe that this is compact! \(\square\)

Definition 5.6.7 Cartan involutions. \(\sigma\) is called a Cartan involution if \(G^\sigma\) is compact, i.e. \(G^\sigma(\mathbb{R})\) is compact and meets every connected component of \(G^\sigma(\mathbb{C})\).

Theorem 5.6.8 Let \(G\) be connected, then \(G\) is reductive iff \(G\) admits a Cartan involution.

Lemma 5.6.9 for next time. If \(K\) is a compact lie group then any \(\mathbb{C}\)-representation \(V\) of it admits a \(K\)-invariant pos. def. Hermitian form.
Conversely if \(K\) has a faithful representation admitting a \(K\)-inv pos. def. Herm. form. then \(K\) is compact.
Proof. \(K\) compact, take any \(H_0(u, v)\) a pos. def. herm. form on \(V\). Then
\[H(u, v) = \int_K H_0(Ku, Kv) \, dK\]
is \(K\)-invariant with some properties. For the converse statement the conditions imply \(K \hookrightarrow U(K)\) hence \(K\) is compact. \(\blacksquare\)

Remark 5.6.10 One source of involutions on \(G\) come from \(C \in G \setminus Z\) s.t. \(C^2 \in Z\) then
\[g \mapsto CG^{-1}\]
is such an involution. e.g. \(J!!\)

5.7 What is ... a Shimura Variety? (Angus)

Motivation. We began by studying modular curves e.g. \(Y_0(N) = \Gamma_0(N) \backslash \mathcal{H}\)
Aash proved
\[Y_0(N) = \Gamma_0(N) \backslash \text{SL}_2(\mathbb{R}) / \text{SO}_2(\mathbb{R}).\]
Consider \(A = \prod_v \mathbb{Q}_v\) the adele ring of \(\mathbb{Q}\). Let
\[K_0(N) = \left\{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \text{GL}_2(\hat{\mathbb{Z}}) : c \equiv 0 \pmod{N}, \, c \text{ mod } N \right\}.\]

Theorem 5.7.1 Strong approximation.
\[\text{GL}_2(A) = \text{GL}_2(\mathbb{Q}) \text{GL}_2(\mathbb{R})^+ K_0(N).\]

Corollary 5.7.2
\[Y_0(N) = \text{GL}_2(\mathbb{Q}) \text{Z(GL}_2(\mathbb{A})) \backslash \text{GL}_2(\mathbb{A}) / K_0(N) \text{SO}_2(\mathbb{R})\]
We will generalise this final viewpoint for general \(G\).
Last time \(X = \text{conjugacy class of morphisms}\)
\[h: S \to G\] for \(G/R\)
an algebraic group s.t.
1.
\[h(\mathbb{R}^\times) \subseteq Z(G(\mathbb{R}))\]
2. The hodge structure on Lie(G) induced by \( \text{ad} \circ h \) is of type \{(-1, 1), (0, 0), (1, -1)\).

We also began studying Cartan involutions. Take an involution \( \sigma \) of \( G \) and define
\[
G^\sigma(A) = \{ g \in G(A \otimes \mathbb{C} : \sigma(g) = \bar{g} \}
\]
this \( G^\sigma \) is another algebraic group /\( \mathbb{R} \).

**Remark 5.7.3** \( G^\sigma \) is a real form of \( G \), i.e. \( G^\sigma \otimes \mathbb{C} = G \otimes \mathbb{C} \).

**Example 5.7.4** \( G = GL_n, \sigma(g) = (g^T)^{-1} \) then \( G^\sigma = U(n) \). □

Recall the definition of a Cartan involution.

For \( C \in G(\mathbb{R}) \) s.t. \( C^2 \in Z(G(\mathbb{R})) \) then
\[
\sigma: g \mapsto CgC^{-1}
\]
is an involution.

When is it Cartan?

**Definition 5.7.5** An \( \mathbb{R} \)-representation \( V \) of \( G \) is \( \mathbb{C} \)-polarizable if there exists a \( G \)-invariant bilinear form
\[
\Psi: V \times V \to \mathbb{R}
\]
s.t.
\[
\Psi(x, Cy)
\]
is symmetric and positive definite. ♦

**Theorem 5.7.6** Let \( G/\mathbb{R} \) be an algebraic group. Let \( C \in G(\mathbb{R}) \) s.t. \( C^2 \in Z(G(\mathbb{R})) \).
Let \( \sigma: g \mapsto CgC^{-1} \) then \( \sigma \) is a Cartan involution iff \( G \) admits a faithful \( \mathbb{C} \)-polarizable representation.

**Proof.** \( \Rightarrow \). Assume \( G^\sigma \) is compact. Let \( V \) be a faithful \( \mathbb{R} \)-representation of \( G^\sigma(\mathbb{R}) \).
From last time, there exists a \( G^\sigma(\mathbb{R}) \)-invariant positive definite symmetric form
\[
\Psi: V \times V \to \mathbb{R}
\]
consider \( \Phi(u, v) = \Psi(u, C^{-1}v) \). Then \( \Phi(x, Cy) \) is positive definite and symmetric so \( \Phi \) is a \( \mathbb{C} \)-polarization.

\( \Leftarrow \). Let \( V \) be \( \mathbb{C} \)-polarizable so we have \( \Psi: V \times V \to \mathbb{R} \). Then \( \Psi_C: V_C \times V_C \to \mathbb{C} \) is symmetric bilinear \( G \)-invariant. Let \( H(u, v) = \Psi_C(u, \bar{v}) \) consider \( H^\sigma(u, v) = H(u, Cv) \).

\( H^\sigma \) is \( G^\sigma(\mathbb{R}) \)-invariant positive definite, Hermitian. From last time \( G^\sigma \) is compact. ■

Now introduce polarizations on Hodge structures.

**Definition 5.7.7** A polarization on a weight \( k \) Hodge structure
\[
h: S \to \text{GL}(V)
\]
\[
V_C = \bigoplus_{p+q=k} V^{p,q}
\]
is a bilinear form \( \Psi: V \times V \to \mathbb{R} \) s.t.

1. \( \Psi \) is (symmetric/alternating) if \( k \) is even / odd.

2. Letting
\[
H: V_C \times V_C \to \mathbb{C}
\]
be given by
\[
H(u, v) = i^k \Psi(u, \bar{v})
\]
then the
\[ V_{p,q} \]
are orthogonal with respect to \( H \) and \( H|_{V_{p,q}} \) has sign \( i^{p-q-k} \).

Why polarize?
Recall: the set of polarized Hodge structures on \( \mathbb{R}^{2g} \) of type \( \{(-1,0), (0,-1)\} \) is the Siegel upper half space \( \mathcal{H}_g \).

**Lemma 5.7.8** Let \( \mathbb{R}(n) \) be the vector space \( \mathbb{R} \) with Hodge structure \( z \mapsto |z|^n \). A bilinear form \( \Psi \) on \( V \) (of weight \( k \)) is a polarization iff
1. \( \Psi: V \times V \to \mathbb{R}(-k) \) is a morphism of Hodge structures.
2. \( \Psi(v, h_i(w)) \) is symmetric and positive definite.

**Proof.** \( \Leftarrow \) in Jared’s notes.
\( \Rightarrow \), we want to show
\[
\Psi(h(z)v, h(z)w) = |z|^{-k} \Psi(v, w)
\]
\[
\Psi(h(z)v, h(z)w) = i^{-k} H(h(z)v, h(z)w)
\]
\[
= i^{-k} H(h(z) \sum p,q, \sum h(z)w_{pq})
\]
\[
= \cdots
\]
\[
= |z|^{-k} \Psi(v, w)
\]
using orthogonality. \( \blacksquare \)

Let \( V \) be a faithful representation of \( G \) s.t. for all \( h \in X \) we get a Hodge structure on \( V \).
Call \( V \) polarizable if in the weight decomposition
\[
V = \bigoplus_k V_k
\]
each \( V_k \) admits a bilinear form \( \Psi_k \) s.t. \( h \in X \) gives a polarized Hodge structure on \( V_k \).

To define the adjoint group, take the adjoint representation
\[
\text{ad}: G_1^{ad} = \text{ad}(G_1)
\]
if \( G_1 \) is connected then \( G_1^{ad} = G_1/Z(G_1) \).

**Theorem 5.7.9** Let \( G_1 \) be the smallest subgroup of \( G \) through which all the \( h \in X \) factor. A faithful representation \( V \) is polarizable iff
1. \( G_1 \) is reductive.
2. For some \( h \in X \) (equivalently for all \( h \in X \)) conjugation by \( h(i) \) is a Cartan involution on the adjoint group \( G_1^{ad} \).

**Proof.** \( \Rightarrow \) Let \( G_2 \subseteq G_1 \) be the smallest subgroup containing \( h(U^1) \) for all \( h \in X \) where \( U^1 = \{|z| = 1\} \subseteq \mathbb{C}^\times \). Then \( G_1 \) is generated by \( G_2 \) and \( h(t) \) for all \( t \in \mathbb{R}^* \), \( h \in X \). Since \( h(t) \) is always central have \( G_1^{ad} = G_2^{ad} \). By the previous lemma, \( \forall z \in U^1 \)
\[
\Psi(h(z)v, h(z)w) = \Psi(v, w)
\]
so \( \Psi \) is \( G_2 \) invariant. Further \( \Psi(v, h(i)w) \) is symmetric positive definite for all \( h \in X \). So conjugation by \( h(i) \) is a Cartan involution on \( G_2 \) so on \( G_2^{ad} = G_1^{ad} \). \( \blacksquare \)
**Definition 5.7.10** Shimura data. A **Shimura datum** is a pair \((G, X)\) where
1. \(G/\mathbb{Q}\) is a reductive algebraic group.
2. \(X\) is a \(G(\mathbb{R})\)-conjugacy class of morphisms \(h: S \rightarrow G_{\mathbb{R}}\) s.t.
   (a) \(\forall h \in X\) the Hodge structure on \(\text{Lie}(G_{\mathbb{R}})\) induced by \(\text{ad} \circ h\) is of type \((-1, 1), (0, 0), (1, -1)\).
   (b) The involution \(\text{ad} h(i)\) (i.e. conjugation by \(h(i)\)) is a Cartan involution on \(G^{\text{ad}}\).
   (c) \(G\) has no \(\mathbb{Q}\)-factor on which the projection of \(h\) is trivial.

**Definition 5.7.11** Let \(A_\infty^\prime = \prod_{p = \infty}^\prime \mathbb{Q}_p\) be the ring of finite adeles of \(\mathbb{Q}\). Let \(K \subseteq G(A_\infty^\prime)\) be a compact open subgroup. The Shimura variety of level \(K\) then
\[
\text{Sh}_K(G, X) = G(\mathbb{Q}) \backslash X \times G(A_\infty^\prime) / K
\]
The Shimura variety at infinite level is
\[
\text{Sh}(G, X) = \lim_{\leftarrow} G(\mathbb{Q}) \backslash X \times G(A_\infty^\prime) / K = G(\mathbb{Q}) \backslash X \times G(A_\infty^\prime)
\]

**Example 5.7.12** \(GL_2\). \(X = \text{conj. class containing } h: (a+bi) \mapsto \begin{pmatrix} a & b \\ -b & a \end{pmatrix} \leftrightarrow \mathbb{C} \setminus \mathbb{R} \leftrightarrow \{ \text{complex structures on } V = \mathbb{Q}^2 \}.
\(h \mapsto i\)
Let \(E/\mathbb{C}\) be an elliptic curve. We have the full Tate module
\[
TE = \lim_{\leftarrow} E[N] \simeq \hat{\mathbb{Z}}^2
\]
We have the full rational Tate module
\[
V^\infty E = TE \otimes A_\infty^\prime \simeq (A_\infty^\prime)^2
\]
\[
\simeq H^1(E, \mathbb{Q}) \otimes A_\infty^\prime
\]

**Proposition 5.7.13** \(\text{Sh}(GL_2, X)\) classifies isogeny classes of pairs \((E, \eta)\) where
\(E/\mathbb{C}\) an elliptic curve
\[
\eta: A_\infty^\prime \times A_\infty^\prime \rightarrow V^\infty(E)
an A_\infty^\prime\text{ linear isomorphism.}
\]

**Remark 5.7.14** An isogeny is \(f \in \text{Hom}(E, E') \otimes \mathbb{Q}\) sending \(\eta \mapsto \eta' \text{ Sh}(GL_2, X)\) has components indexed by \(\hat{\mathbb{Z}}^\times\).
5.8 Canonical models (Alex)

Recall we defined Shimura varieties given a Shimura datum \((G, X)\) and a compact open \(K \subseteq G(\mathbb{A}^\infty)\) as

\[ \text{Sh}_K(G, X) = \frac{G(\mathbb{Q}) \backslash (X \times G(\mathbb{A}^\infty))}{K} \]

a quasi-projective variety, and more generally the infinite level version

\[ \text{Sh}_K(G, X) = \lim_{\leftarrow K} \frac{\text{Sh}_K(G, X) = G(\mathbb{Q}) \backslash (X \times G(\mathbb{A}^\infty))}{K} \]

which is a pro-variety and in fact a scheme.

These are varieties over \(\mathbb{C}\), we might hope to define them over a number field or even a ring of integers, so that we can do number theoretic things (look locally prime by prime for instance, or identify special rational points).

In the case where our Shimura variety is a natural moduli space (modular curves) might expect that this is indeed possible.

There will be two words in this talk, special and canonical that already have a vague meaning, we will be giving them a precise meaning in this talk for once!

5.8.1 Galois descent

Say you have a variety over \(\mathbb{C}\). Is it really a \(\mathbb{C}\)-variety, or is it a \(k\) variety for \(k \subseteq \mathbb{C}\) that has been base-changed to \(\mathbb{C}\)?

**Question 5.8.1** Given \(X/\mathbb{C}\) a variety, is there a subfield \(k \subseteq \mathbb{C}\) and an \(X_0/k\) with

\[ X \approx X_0 \times_k \mathbb{C} \]

we then say \(X\) descends to \(k\), and that \(X_0\) is a model of \(X\) over \(k\).

**Preview: some examples of curves.**

**Example 5.8.2** Let

\[ C : x^2 + y^2 = \pi/\mathbb{C} \]

is there \(C_0/\mathbb{Q}\) s.t. \(C_0 \times_{\mathbb{Q}} \mathbb{C} \approx C\). Yes, we have

\[ C \approx x^2 + y^2 = 1/\mathbb{C} \approx (x^2 + y^2 = 1/\mathbb{Q}) \times_{\mathbb{Q}} \mathbb{C}. \]

**Example 5.8.3** Let now

\[ E : y^2 = x^3 + ix + 1/\mathbb{C} \]

is there some \(E_0/\mathbb{Q}\) such that

\[ E_0 \times_{\mathbb{Q}} \mathbb{C} \approx E? \]

If there was such the following would be true: For any \(\sigma \in \text{Gal}(\mathbb{C}/\mathbb{Q})\) we have

\[ \begin{array}{ccc}
E_0 & \xrightarrow{f_{\sigma}} & E' \\
y^2 = x^3 + \sigma(i)x + 1 & \yrightarrow{f_{\sigma}} & y'^2 = x^3 + (i)x + 1
\end{array} \]

but two elliptic curves are isomorphic (over \(\mathbb{C}\)) if and only if they have the
same \( j \)-invariant.

\[
    j(E) = 1728 \frac{4i^3}{4i^3 + 27} = 1728 \left( 1 + \frac{-27}{-4i + 27} \right)
\]

\[
    j(E^\sigma) = 1728 \frac{4\sigma(i)^3}{4\sigma(i)^3 + 27} = \sigma(j(E))
\]

so these curves are not isomorphic over \( \mathbb{Q} \), no way does it come from a \( \mathbb{Q} \)-curve. \( \square \)

This example suggests another interesting behaviour, the curve over \( \mathbb{C} \) could come from a \( k \)-curve in multiple ways, which are non-isomorphic over the base.

Example 5.8.4 Let now

\[
    E: y^2 = x^3 + x + 1/\mathbb{C}
\]

we have

\[
    E_0: y^2 = x^3 + x + 1/\mathbb{Q}
\]

duh... but also

\[
    E'_0: 2y^2 = x^3 + x + 1 \Rightarrow y^2 = x^3 + 4x + 8/\mathbb{Q},
\]

both are isomorphic to \( E \) over \( \mathbb{C} \) but are not isomorphic to each other over \( \mathbb{Q} \). \( \square \)

Coming back to our necessary condition:

Question 5.8.5 If for all \( \sigma \in \text{Gal}(\mathbb{C}/k) \) we have some

\[
    f_\sigma: X \xrightarrow{\sim} X^\sigma
\]

does \( X \) descend to \( k \)? \( \square \)

For elliptic curves we have \( j(E^\sigma) = \sigma(j(E)) \) so \( E \cong E^\sigma \) for all \( \sigma \) implies \( j(E) \in k \) and hence there is an elliptic curve \( E_0/k \) with \( j(E_0) = j(E) \) hence they are isomorphic over \( \mathbb{C} \), explicitly:

\[
    y^2 + xy = x^3 - \frac{36}{j(E) - 1728} x - \frac{1}{j(E) - 1728}
\]

when \( j \neq 0, 1728 \).

So our necessary condition is sufficient for genus 1 (exercise: genus 0).

Now I will subtly switch to quasiprojective-variety-land.

Notice however that given

\[
    X_0/k
\]

so that we have natural

\[
    (X_0 \times_k \mathbb{C}) \xrightarrow{f_\sigma \circ \sim} (X_0 \times_k \mathbb{C})^\sigma
\]

various isomorphic curves, we have the relation

\[
    f_\sigma^T f_\tau = f_{\sigma \tau}.
\]

Theorem 5.8.6 Weil 1956. \( X/\mathbb{C} \) descends to \( k \) if and only if we can find \( f_\sigma \) as above satisfying a cocycle condition

\[
    f_{\sigma \tau} = (f_\tau)^\sigma f_\sigma: X \rightarrow X^\sigma \rightarrow X^{\sigma \tau},
\]

such a system is called a Weil descent datum.
This condition sounds like it could be irritating to check, fortunately we have the following:

**Remark 5.8.7** If \( X / C \) has no automorphisms (i.e. a generic genus \( g \geq 3 \) curve) then the cocycle condition is trivial and we just need the isomorphisms as in our first necessary condition. This is as \( f^{-1} f \sigma f f \sigma \) is just some automorphism, we want it to be the identity.

Unfortunately many curves of interest have a lot of automorphisms however. Like superelliptic curves/cyclic covers.

This motivates the following definition:

**Definition 5.8.8 Field of moduli.** The field of moduli of \( X / C \) is the fixed field of
\[
\{ \sigma \in \text{Gal}(C/Q) : X^\sigma \cong X \}.
\]

It would be great if every curve could be defined over its field of moduli.

"You can’t always get what you want, but if you try sometimes, you might find, you get what you need" - The philosopher Jagger.

**Example 5.8.9 Shimura.** Let \( m \) be odd and define a hyperelliptic curve of genus \( m-1 \) (which is even) as
\[
X: y^2 = a_0 x^m + \sum_{r=1}^{m} (a_r x^{m+r} + (-1)^r a^0_r x^{m-r}), \ a_i \in C, \ a_m = 1, \ a_0 \in R
\]
\( \rho \) is complex conjugation, then we have an isomorphism
\[
\mu: X \rightarrow X^\rho, \ \mu(x, y) = (-x^{-1}, ix^{-m}y)
\]
\[
\rho \mu: (x, y) \mapsto (x, -y)
\]
so the field of moduli is contained in \( R \). As long as we pick all \( a_i, a^0_i \) algebraically independent over \( Q \) there are no automorphisms except \( \pm 1 \). Exercise, in this case \( X \) has no model over \( R \).

Warning even though trivial automorphism group is best, it is not really the case that more automorphisms is worse for you.

What does help is points

**Theorem 5.8.10 Weil 1956, Milne 14.6.** \( X / C \) descends to \( k \) if all \( X^\sigma \cong X \) and there exists a set of points \( P_1, \ldots, P_n \in X(C) \) s.t.

1. The only automorphism of \( X \) fixing each \( P_i \) is the identity.

2. There exists a subfield \( L \subseteq C \) finitely generated \( / k \) s.t. \( \sigma P_i = P_i \) for all \( \sigma \) fixing \( L \).

Goal. Identify a special set of points, and some field \( L \) as above where we “know” the galois action.

**5.8.2 Reflex fields**

First we define a field based on a Shimura datum, this will (eventually) be the field we hope to descend the associated Shimura variety to.

**Definition 5.8.11 Algebraic tori.** An algebraic torus over a field \( k \) is an algebraic group \( T \) such that \( T_k \cong (G_m)^n \).
Let $G/\mathbb{Q}$ be reductive, $k \subseteq \mathbb{C}$ and let

$$C(k) = G(K) \setminus \text{Hom}(G_m, G_k)$$

be the set of conj. classes of cocharacters $/k$.

For $(G, X)$ a Shimura datum we can take $X \ni x \mapsto \mu_x(z) = h_x(c(z, 1) \in C(\mathbb{Q}^{\text{alg}}) \subseteq C(\mathbb{C})$.

So think of $c(X) \in C(\mathbb{Q}^{\text{alg}})$

**Definition 5.8.12 Reflex fields.** The reflex field, denoted $E(G, X)$ is the field of definition of $c(X)$ inside $\mathbb{Q}^{\text{alg}}$.

**Fact 5.8.13** Any field of definition of $G$ contained in $\mathbb{Q}^{\text{alg}}$ is contained in $E(G, X)$.

### 5.8.3 Special points

In the theory of modular curves and the upper half plane there are certain points that play an important role, imaginary quadratic integers in $\mathbb{H}$.

Why are these points special? They are fixed points: if we try and solve for $z \in \mathbb{H}$

$$z = \begin{pmatrix} a & b \\ c & d \end{pmatrix} z = \begin{pmatrix} az + b \\ cz + d \end{pmatrix}$$

we get

$$cz^2 + (d-a)z - b = 0$$

which has discriminant $(d-a)^2 + 4cb = d^2 - 2ad + a^2 + 4bc = (a+d)^2 - 4(ad - bc) = \text{Tr}^2 - 4 \det$ so $z$ is an eigenvalue of this matrix. (note that a matrix must be elliptic to have fixed points in the upper half plane).

In fact this is a general phenomenon:

**Definition 5.8.14 Special points.** $x \in X$ is a special point if there is a $\mathbb{Q}$-torus $T \subseteq G$ s.t.

$$h_x(\mathbb{C}^*) \subseteq T(\mathbb{R})$$

we also say $(T, x)$ is a special pair.

**Remark 5.8.15** $(T, x)$ special means $T(\mathbb{R})$ fixes $x$.

Conversely if $T$ is a maximal torus of $G$ with $T(\mathbb{R})$ fixing $x$ then $h_x(\mathbb{C}^*)$ is in the centraliser of $T(\mathbb{R})$ inside $G(\mathbb{R})$ which is itself $\Rightarrow$ $(T, x)$ is special.

I said this generalises CM points, how?

**Example 5.8.16** Let $G = \text{GL}_2$ and $\mathbb{H}_1^+ = \mathbb{C} \setminus \mathbb{R}$ then we have our old friend the $G(\mathbb{R})$ action

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix} z = \begin{pmatrix} az + b \\ cz + d \end{pmatrix}$$

so if $z \in \mathbb{C} \setminus \mathbb{R}$ generates an imaginary quadratic field $E/\mathbb{Q}$ (which is a 2-d $\mathbb{Q}$-vector space) we can embed

$$E \hookrightarrow \text{Mat}_2(\mathbb{Q})$$

using basis $(1, -z)$ for $E$.

So we get a maximal subtorus $T = \text{Res}_{E/\mathbb{Q}}(G_m) \subseteq G$.

Now

$$E \otimes \mathbb{C} = \langle 1 \otimes 1, 1 \otimes (-z) \rangle$$
and we can map
\[ E \otimes \mathbb{C} \to \mathbb{C} \]
\[ e \otimes z \mapsto ez \]
we have a kernel of dimension 1
\[ \langle z \otimes 1 + 1 \otimes (-z) \rangle = \langle \begin{pmatrix} z \\ 1 \end{pmatrix} \rangle \]
exercise check Res_{E/Q}(G_m)(R). \qed

5.8.4 Canonical models

Given a special pair \((T, x) \subset (G, X)\) we have a cocharacter \(\mu_x\) of \(T\) defined over \(E(x)\) we can form the map
\[ r_x: E_{E(x)}^\times \to T(A) \]
the last map just forgets the infinite components.

We have the artin map from CFT
\[ \text{art}_{E(x)}: E_{E(x)}^\times \to \text{Gal}(E(x)^{ab}/E(x)) \]
\[ r_x: E_{E(x)}^\times \to T(A_f). \]

Call \([x, a]_K\) the point of \(\text{Sh}_K(G, X)\) represented by \((x, a)\).

**Definition 5.8.17** Milne 12.8. Let \((G, X)\) be a Shimura datum, and let \(K\) be a compact open subgroup of \(G(A_f)\). A model \(M_K(G, X)\) of \(\text{Sh}_K(G, X)\) over \(E(G, X)\) is a **canonical model** if, for every special pair \((T, x) \subset (G, X)\) and \(a \in G(A_f), [x, a]_K\) has coordinates in \(E(x)^{ab}\) and
\[ \sigma[x, a]_K = [x, r_x(s)a]_K \]
for all
\[ \sigma \in \text{Gal}(E(x)^{ab}/E(x)) \]
\[ s \in E_{E(x)}^\times \]
\[ \text{art}_{E(x)}(s) = \sigma \]
In other words, \(M_K(G, X)\) is canonical if every automorphism \(\sigma\) of \(\mathbb{C}\) fixing \(E(x)\) acts on \([x, a]_K\) according to the above rule, where \(s\) is any idele such that
\[ \text{art}_{E(x)}(s) = \sigma|E(x)^{ab}. \]

**Example 5.8.18** \(T\) an algebraic torus over \(\mathbb{Q}\) and
\[ h: S \to T_R \]
then \((T, h)\) is a Shimura datum \(E = E(T, h)\) is the field of definition \(\mu_h\) in this case
\[ \text{Sh}_K(T, h) = T(\mathbb{Q})/\{h\} \times T(A_f)/K \]
is a finite set, defines a continuous action of
\[ \text{Gal}(E^{ab}/E) \cup \text{Sh}_K(T, h). \]
this action defines a model of $\text{Sh}_K(T, h)$ over $E$ which by definition is canonical.

\[\blacksquare\]

**Theorem 5.8.19** Langlands conjecture, Milne 1983. Let $(G, X)$ be a shimura datum, $\sigma$ an automorphism of $\mathbb{C}$. Langlands defined

\[(G^\sigma, X^\sigma)\]

and conjectured a unique isomorphism

\[f_\sigma : \text{Sh}(G^\sigma, X^\sigma) \to \text{Sh}(G, X)\]

satisfying some conditions. Then the $f_\sigma$ for $\sigma \in \text{Gal}(\mathbb{C}/E(G, X))$ are a descent datum, and the model is canonical.

**Theorem 5.8.20** For any Shimura datum $(G, X)$, $\text{Sh}_K(G, X)$ has a canonical model (defined to be a compatible system of canonical models for $\text{Sh}_K$). The canonical model is unique up to unique isomorphism.

Chapter 6

Gross-Zagier

These are notes for BUNTES Fall 2019, the topic is Gross-Zagier, they were last updated September 10, 2019. For more details see the webpage. These notes are by Alex, feel free to email me at alex.j.best@gmail.com to report typos/suggest improvements, I’ll be forever grateful.

6.1 An Overview of Gross-Zagier and Related Objects / Formulas of interest (Sachi)

Goal today is to motivate and give some high level overview of the objects in Gross-Zagier. It involves many things $L$-functions, elliptic curves, modular forms.

Main reference: [94].

6.1.1 A big example

Today we will study

$$E: y^2 + y = x^3 + x^2$$

LMFDB label 43.a1, http://lmfdb.xyz/EllipticCurve/Q/43.a1/.
One fundamental invariant we can compute is the conductor, in this case 43, we only have bad reduction at 43 and no other prime.
To compute the real period we can transform to short Weierstrass form.

\[ y^2 = x^3 - 432x + 15120 \]

then we have invariant differential

\[ \frac{dx}{2y} = \frac{dx}{2\sqrt[3]{x^3 - 432x + 15120}}. \]

Real period is then

\[ \omega_1 = \int_{E(R)} \frac{dx}{2y} \approx 5.4687 \ldots \]

For \( E/C \) fix a complex conjugate root of \( E, \alpha, \) and \( \beta = \) real root.

\[ \omega_2 = \int_{\alpha}^{\beta} \frac{dx}{2y} \]

\[ = 2.73434476498379 + 1.36318241817043i \]

We can look at \( E/F_p \) for various \( p \). Obtained by looking at the equation \( y^2 + y = x^3 + x^2 \) (mod \( p \)) for various \( p \).

At 43 we have non-split multiplicative reduction, which means that we have a singular curve with tangent slopes not defined over \( F_{43} \).
\[ L_E = \left( \frac{1}{1 + 43^{-2s}} \right) \prod_{p \neq 43} \frac{1}{1 - (N_p - p - 1)p^{-s} + pp^{-2s}} \]
\[ = \sum_{n \geq 1} \frac{a_n}{n^s} \]

We can tabulate the \( a_n \)

**Table 6.1.3 \( a_n \) s**

\[
\begin{array}{ccccccccccc}
 n & 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 \\
 a_n & 1 & -2 & -2 & 2 & -4 & 4 & 0 & 0 & 1 \\
\end{array}
\]

As we have \( E/\mathbb{Q} \) we can determine that

\[ E(\mathbb{Q}) \cong \mathbb{Z} \cdot \frac{P}{=(0,0)} \]

Next up the Néron-Tate canonical height:

\[ \hat{h}(P) = \lim_{n \to \infty} \frac{\log(h_{naive}(2^n P))}{4^n} \]

naive height is the max of the absolute values of the numerator and denominator of the \( x \)-coordinate. In our case this is

\[ \hat{h}(P) \approx 0.0628165070875. \]
We have the Hasse-Weil bound:
\[ |N_p - p + 1| < 2\sqrt{p} \]
so the L-function converges for \( R(s) > 3/2 \). So modularity implies that \( L_E(s) \) extends to an entire function \( \widetilde{L}_E \) satisfying a functional equation
\[ \widetilde{L}_E(s) = -\widetilde{L}_E(2 - s) \]
in particular \( \widetilde{L}_E(s) \) vanishes at \( s = 1 \).

**BSD for rank 1 then says:**

1. \( \text{ord}_{s=1} \widetilde{L}_E(s) = \text{rank } E(\mathbb{Q}) = 1 \)
2. \( \frac{d}{ds} \widetilde{L}_E(s)|_{s=1} = \hat{h}(P)\omega_1 \| \text{III} \|
\approx 0.34352397 \)

| III | is predicted to be finite (in which case the order is a square). the LHS can be computed using
\[ 2 \sum_{n=1}^{\infty} a_n \int_1^{\infty} \log t \exp \left( -\frac{2n\pi t}{\sqrt{43}} \right) dt. \]

**Modularity.** Goal: Verify \( E \) is modular. Two definitions today:

1. There exists a newform \( f \in S_2(\Gamma_0(N)) \) with fourier coefficients the same as the \( L \)-series:
\[ a_p(f) = a_p(E) \]
for all \( p \not| N \).
2. There exists \( X_0(N) \to E \) finite defined over \( \mathbb{Q} \).

Consider \( X_0(43) \)
the modular curve for the congruence subgroup generated by \( \Gamma_0(43) = \left( \begin{array}{cc} a & b \\ c & d \end{array} \right) \)
with \( c \equiv 0 \) (mod 43).
\[ w_{43} = \left( \begin{array}{cc} 0 & -1 \\ \sqrt{43} & 0 \end{array} \right) \]
\[ \Gamma_0(43)^+ \backslash \mathbb{H} \simeq \text{genus 1 curve} \]
which is potentially equal to \( E \).

Strategy: Find \( \eta, \xi \) s.t.
\[ \eta(\tau)^2 + \eta(\tau) = \xi(\tau)^3 + \xi(\tau)^2 \]
and
\[ \frac{d\eta}{2\xi + 1} = f(q) \frac{dq}{q} \]
\[ \xi f^2, \eta f^3 \]
should be holomorphic modular forms in \( M_4(\Gamma_0(43)) \) and \( M_6(\Gamma_0(43)) \). we can compute \( q \)-series expansions and use modular symbols to prove they exist.
**Quadratic twists of** $E$. Let $\Delta < 0$ be a fundamental discriminant.

$$E: y^2 = f(x)$$

then

$$E_\Delta: \Delta y^2 = f(x)$$

these are not isomorphic over $\mathbb{Q}$.

The $L$-function of $E_\Delta$. For any $\Delta$ coprime to 43

$$L_{E_\Delta}(s) = \sum_{n \geq 1} \left( \frac{\Delta}{n} \right) \frac{a_n}{n^s}$$

can prove that for $p \nmid 6 \cdot 43 \cdot \Delta$.

$$a_p(E) \leftrightarrow a_p(E_\Delta)$$

are related by considering

$$E: y^2 = f(x)$$

$$E_\Delta: \Delta y^2 = f(x)$$

mod $p$, so if $\Delta$ is a square we have isomorphisms locally and the $a_p$ are equal, otherwise all non-square and squares are swapped.

BSD says

$$L_{E,\Delta}(1) = \Omega_{E,\Delta}^+ \prod_p c_p A_\Delta$$

if rank = 0.

Waldspurger’s implies that $A_\Delta$ is a square.

**Theorem 6.1.4 Gross-Zagier.** If $\Delta < 0$ is a fundamental discriminant which is a square mod 43, then

$$\hat{h}(P_\Delta) = \frac{\sqrt{|\Delta|}}{8\pi^2 \|f\|} L_E'(1)L_{E,\Delta}(1),$$

where $P_\Delta$ is the Heegner point on $E$ associated to the discriminant $\Delta$.

Adding in Waldspurger we get

$$A(\Delta) = c_\Delta^2$$

$$\hat{h}(P_\Delta) = \hat{h}(b_\Delta P) = b_\Delta^2 \hat{h}(P)$$

but also

$$\hat{h}(P_\Delta) = \frac{\sqrt{|\Delta|}}{8\pi^2 \|f\|} L_E'(1)\Omega_{E,\Delta}^+ \prod_p c_p c_\Delta^2$$

as $\Omega_{E,\Delta}^+ = \Omega_E^- / \sqrt{\Delta}$ we have cancellation and $c_\Delta^2 = b_\Delta^2$ for all $\Delta$.
